4. PERMITTED EMISSIONS TABLE

Purpose

The purpose of this table is to document the permitted emissions for this stationary source. Rule 29, "Conditions on Permits," requires permitted emissions to be included on each Permit to Operate. Rule 29 is not federally enforceable.

The permitted emissions table also characterizes the amount and type of criteria air pollutants emitted by this stationary source.

Rule 29 requires that annual permitted emissions be based on a 12 calendar month rolling period and be expressed in units of tons per year. Hourly permitted emissions are required to be expressed in units of pounds per hour. Permitted emissions for a stationary source are required to be determined by aggregating the permitted emissions for each emissions unit at the stationary source.

In general, permitted emissions are calculated based on throughput or consumption data for an emission unit, specific physical characteristics of the emission unit, and emission factors. The emission factors may be standard published emission factors, or they may be derived from source test data or specific emission limits that apply to the emissions unit. In some cases, permitted emissions are expressed directly as a set of pollutants and emission limits in tons per year without reference to any calculation method.

Section No. 3, "Permitted Throughput and Consumption Limit Table," contains information on the throughput and consumption limits that are enforceable at this stationary source. In addition, other sections of this permit contain conditions that act to enforce specific portions of the permitted emissions table.

Equipment Description

This portion of the table is the same as the equipment description in the "Permitted Equipment and Applicable Requirements Table."

Tons Per Year

This column of the table represents the permitted emissions in units of tons per year for ROC (reactive organic compounds), NO_x (nitrogen oxides), PM (particulate matter), SO_x (sulfur oxides), and CO (carbon monoxide). In some cases, emissions of non-criteria pollutants of interest may also be listed. Pursuant to Rule 29, annual permitted emissions shall be the annual emissions used to determine compliance for issuance of any new or revised permit issued after October 22, 1991. For emissions units for which no new or revised permit has been issued since

October 22, 1991, annual permitted emissions generally reflect actual historical emissions from the emissions unit.

The permitted emissions limit may apply to a single emissions unit or to a set of emission units. When the limit applies to set of emissions units, the set consists of the emissions unit with which the limit is listed and the emissions units which follow that have an asterisk in the pollutant columns.

Pounds Per Hour

This column of the table represents the permitted emissions in units of pounds per hour for ROC (reactive organic compounds), NO_x (nitrogen oxides), PM (particulate matter), SO_x (sulfur oxides), and CO (carbon monoxide). Pursuant to Rule 29, hourly permitted emissions shall be calculated based on the maximum quantity of each air pollutant which may be emitted from the emissions unit during a one-hour period, as limited by any applicable rules or permit conditions.

Hazardous Air Pollutants

This permit does not provide information that characterizes the emissions of hazardous air pollutants (HAPS) from this facility. This information can be obtained from the reissuance application or the facility's AB-2588, Air Toxics "Hot Spots," Report referenced at the bottom of the "Permitted Emissions Table." For Outer Continental Source (OCS) sources and other sources not subject to AB-2588, HAP emissions information is included in the permit reissuance application and is maintained by the stationary source.

5. OIL WELL LIST

This permit authorizes the operation of a maximum number of wells for the production of oil or natural gas. This section of the permit contains a list of the wells currently authorized to be operated. When changes to the list are desired, the permit holder is required to submit an application to modify the Part 70 Permit.

An Authority to Construct is also required prior to adding a well that is newly drilled to the oil well list or prior to increasing the number of wells on the oil well list.

Section No. 8, "Permit Specific Conditions", includes a condition that limits the maximum number of producing wells at this stationary source. If applicable, Section No. 8 also includes a condition that requires best available control technology (BACT) on specific wells that were subject to Rule 26, "New Source Review".

6. EXEMPT EQUIPMENT LIST

Rule 33.2.A.3 (Part 70 Permits - Application Contents) requires the applicant to provide a list of all emissions units located at the stationary source that are exempt pursuant to Rule 23 based on size or production rate. Pursuant to Rule 33.2.A.3, emissions from insignificant activities do not need to be included in the permit application.

This section of the permit contains a table entitled "Insignificant Activities (Exempt Equipment)". This table is a list of insignificant activities (exempt equipment) at the facility that are exempt from permit based on a size or production rate exemption in Rule 23, "Exemptions From Permit". Insignificant Activity is defined in Rule 33.1 (Part 70 Permits – Definitions). The permittee shall provide calculations, usage records, emission records, and/or operational data as necessary to substantiate an activity as insignificant.

This table is presented for informational purposes only. Any changes to this list are not considered to be permit modifications, nor is the list considered to be enforceable. As detailed in Rule 33.2.A.3, this list is required to be submitted with an application for permit reissuance. The general requirements listed in Section No. 9 of this permit may apply to these insignificant activities.

Ventura County Air Pollution Control District
INSIGNIFICANT ACTIVITIES (EXEMPT EQUIPMENT)
 Part 70 Permit No. 00012

| INSIGNIFICANT ACTIVITIES (EXEMPT EMISSION UNITS) | BASIS FOR EXEMPTION (Size/Production Rate) | RULE 23 CITATION |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|------------------|
| Ajax Boiler at Texcon | < 1 MMBTU/Hr | 23.C.1 |
| 40 BHP Perkins Diesel Fired Fire Water Pump Engine | < 50 BHP | 23.D.6 |

M:\TITLE\TV Permits\PO0012\Permit V\Insignificant-rev181.docx

7. SPECIFIC APPLICABLE REQUIREMENTS (ATTACHMENTS)

As discussed in Section No. 2, "Permitted Equipment and Applicable Requirements Table", the emissions units at this stationary source listed in the table have requirements that are specifically applicable to them. The applicable requirements are based on the District's prohibitory rules, federal NSPS (40 CFR Part 60), federal NESHAPS (40 CFR Part 61), and federal NESHAPS/MACT (40 CFR Part 63).

In this section of the permit, the permit conditions that are associated with each specific applicable requirement are listed in an individual attachment. The attachment is identified with the label "Attachment (APCD Rule No. or CFR No.) #" in the lower left corner. Each attachment has an applicability section that describes how and why this attachment applies to the specific emissions unit. The attachment may apply to one or more of the emissions units listed in the Permitted Equipment and Applicable Requirements Table in Section No. 2.

**Ventura County Air Pollution Control District
Rule 71.1.B.1.a Applicable Requirements
Tanks Equipped with Vapor Recovery**

**Rule 71.1, "Crude Oil Production and Separation"
Adopted 06/16/92, Federally-Enforceable**

**Rule 74.10, "Components at Crude Oil and Natural Gas Production and Processing
Facilities"
Adopted 03/10/98, Federally-Enforceable**

Applicability:

This attachment applies to tanks at this stationary source equipped with a vapor recovery system which directs all vapors to a fuel gas system, a sales gas system, or to a flare. Specifically, this attachment applies to all storage tanks in a tank battery including wash tanks, produced water tanks, and wastewater separators, that are used in the production, gathering, storage, processing, and separation of crude oil and natural gas from any petroleum production permit unit prior to custody transfer. This attachment does not apply to portable tanks or other tanks not equipped with vapor recovery.

A tank is defined as a container, constructed primarily of nonearthen materials, used for the purpose of storing or holding petroleum material, or for the purpose of separating water and/or gas from petroleum material. A tank battery is defined as any tank or aggregation of tanks. An aggregation of tanks is considered a tank battery only if the tanks are located so that no one tank is more than 150 feet from any other tank, edge to edge.

The tank's hatches and other inlet and outlet liquid and gas piping connections are considered to be components subject to the leak requirements of APCD Rule 74.10, "Components at Crude Oil and Natural Gas Production and Processing Facilities".

Conditions:

1. Pursuant to Rule 71.1.B.1.a, all tanks shall be equipped with a properly installed, maintained and operated vapor recovery system. The vapor disposal portion of the vapor recovery system shall consist of either a system which directs all vapors to a fuel gas system, a sales gas system, or to a flare that combusts reactive organic compounds.
2. Pursuant to Rule 71.1.D.2, the vapor recovery provisions of Rule 71.1.B.1.a shall not apply during maintenance operations on vapor recovery systems or tank batteries, including wash tanks, produced water tanks and wastewater separators, if the Air Pollution Control District is notified verbally at least 24 hours prior to the maintenance operation and if the maintenance operation will take no more than 24 hours to complete.

3. The tank's hatches and other inlet and outlet gas and liquid piping connections are components subject to the leak requirements of Rule 74.10, "Components at Crude Oil and Natural Gas Production and Processing Facilities".
4. On a quarterly basis, permittee shall monitor the storage tank vapor recovery system to ensure that compliance with Rule 71.1.B.1.a is being maintained. This shall include an inspection of the following components, as applicable, for proper operation: gas compressor, hatches, relief valves, pressure regulators, flare. Permittee shall keep dated records of the quarterly inspections and tank maintenance activities. These records shall be maintained at the facility and submitted to the District upon request.
5. On an annual basis, permittee shall certify that storage tanks at the facility are complying with Rule 71.1.B.1.a. This annual compliance certification shall include verifying that the tanks are equipped with a vapor recovery system.

M:\TITLEV\Attachments updated\711N1.docx

Ventura County Air Pollution Control District
Rules 71.3.B.2.a.1 and 71.3.B.2.b.2 Applicable Requirements
ROC Liquid Loading Facilities
Bottom Loaded Vapor Recovery System To Gas Pipeline
District-Approved Alternative
Primary and Secondary Overfill Protection

Rule 71.3, "Transfer of Reactive Organic Compound Liquids"
Adopted 6/16/92, Federally-Enforceable

Applicability:

This attachment applies to equipment used to transfer reactive organic compound (ROC) liquids with a Modified Reid Vapor Pressure (MRVP) greater than or equal to 0.5 psia. This attachment does not apply to the transfer of gasoline, or to the transfer of ROC liquids via pipeline.

Specifically, this attachment applies to loading facilities that are equipped with a bottom-loaded vapor recovery system that connects to a gas pipeline recovery and distribution system and are equipped with a District-approved alternative primary and secondary overfill protection system.

A loading facility is defined as any aggregation or combination of organic liquid loading equipment which is located so that all the organic liquid loading outlets for such aggregation or combination of loading equipment can be encompassed within any circle of 300 feet in diameter.

Conditions:

1. Pursuant to Rule 71.3.B.2.a.1, no person shall transfer ROC liquids into any ROC liquid delivery vessel without utilizing a bottom-loaded vapor recovery system that prevents the displaced vapors during loading from being released into the atmosphere. The vapor recovery system shall be capable of collecting all ROC vapors, and shall have a vapor return or condensation system that connects to a gas pipeline recovery and distribution system.

2. Pursuant to Rule 71.3.B.2.b.2, no person shall transfer ROC liquids into any ROC liquid delivery vessel without utilizing a combination of overfill devices and/or procedures, submitted in writing to the APCO, that is at least as effective in preventing overfill spillage as the system in Rule 71.3.B.2.b.1. Permittee has submitted an alternative overfill protection system and shall comply with Rule 71.3.B.2.b in the following manner:

In order to meet primary overfill protection requirements, the applicable loading racks shall be equipped with meters that automatically shut off when the preset volume in gallons is loaded. This preset gallon amount is based on the maximum

weight of ROC liquid that can be legally loaded into the delivery vessel. The maximum weight of liquid that can be loaded shall be determined by first weighing the delivery vessel prior to loading, then subtracting its weight from the total legal weight limit, and then dividing the maximum weight by the liquid density (weight per gallon) to get this amount in gallons.

In order to meet secondary overfill protection requirements, the operator shall set the meter initially to a volume in gallons less than that which would indicate a maximum load, and then the operator shall visually check the truck tank level after the meter shuts off the liquid transfer process. The driver shall then determine how much more liquid, if any, can be loaded. The preset fill meter shall also be used for any additional liquid loading.

As an additional precaution, the maximum weight of liquid that can be legally loaded in the delivery vessel shall still allow for additional volume to load more liquid before an overfill condition would occur. This additional volume can equate up to 3500 gallons or more, depending on the type of liquid and delivery vessel being loaded.

3. Pursuant to Rule 71.3.B.2.c, no person shall transfer ROC liquids into any ROC liquid delivery vessel without utilizing either a block and bleed valve system or other connectors with equivalent spill prevention characteristics.
4. Pursuant to Rule 71.3.B.3, any loading operation equipment, vapor recovery system, or other equipment required by Rule 71.3 shall not leak. The vapor recovery system shall be operated and maintained so that it does not cause the pressure in any delivery vessel to exceed 18 inches water gauge or the vacuum to exceed 6 inches water gauge.
5. Pursuant to Rule 71.3.C.1, no person shall transfer ROC liquids into a delivery vessel using loading equipment having a vapor recovery system unless the delivery vessel is leak free and is permanently equipped with:
 - a. A properly installed vapor recovery system that is compatible with the loading facility.
 - b. A pressure-vacuum relief device for each compartment that is set at 90 percent of the maximum, safe pressure and vacuum ratings of the vessel.
 - c. A secondary overfill protection system compatible with the loading operation APCO-approved secondary overfill protection system.
 - d. A loading connector/adaptor that is compatible with those required at the loading facility.

6. Pursuant to Rule 71.3.C.2, no person shall fill an ROC liquid delivery vessel unless the vapor recovery system is properly operating, properly maintained, does not leak, and all hatches are closed during transfer operations.
7. Pursuant to Rule 71.3.D.1, permittee shall annually monitor one complete loading operation for leaks and for proper operation of the loading equipment and delivery vessel vapor recovery and overfill protection systems. In order to detect leaks during the annual operator inspection, the permittee shall utilize an appropriate analyzer calibrated with methane or the alternative screening procedure in EPA Reference Method 21, as detailed in Rule 71.3.G.3.
8. Pursuant to Rule 71.3.D.2, permittee shall notify the District Enforcement Section of the following problems no later than 72 hours after the annual inspection required by Rule 71.3.D.1:
 - a. If any leaks were detected,
 - b. If the vapor recovery system, including any flare or incinerator, was not operating properly,
 - c. If any hatches were opened during the filling operation,
 - d. If the overfill prevention systems malfunctioned, or
 - e. If any spillage of ROC liquid occurred.
9. Pursuant to Rule 71.3.D.3, any leak detected shall be repaired to a leak free state and any vapor recovery system or overfill prevention system found malfunctioning shall be restored to a properly operating condition. These repairs shall be done as soon as practicable but no later than 5 calendar days from the detection date.
10. Pursuant to Rule 71.3.F.1, the operator of any loading equipment equipped with a bottom-loaded vapor recovery system shall maintain a record of the inspection required by Rule 71.3.D.1 and submit this record to the District upon request. These records shall, at a minimum, include the following:
 - a. Date of inspection and operator's initials.
 - b. Name and location of loading equipment and amount of ROC liquid transferred.
 - c. Description of any leak or malfunction of the vapor recovery or overfill prevention systems.
 - d. Date component was repaired and type of repair, if applicable.
 - e. Whether or not delivery vessels hatches are closed during filling and if any spillage occurred.
 - f. Delivery vessel identification and name of delivery company.

**Ventura County Air Pollution Control District
Rule 71.3.E.1 Applicable Requirements
ROC Liquid Loading Facilities
Low Vapor Pressure Exemption**

**Rule 71.3, "Transfer of Reactive Organic Compound Liquids"
Adopted 6/16/92, Federally-Enforceable**

Applicability:

This attachment applies to ROC liquid loading facilities that are exempt from Rule 71.3 requirements, pursuant to the exemption of Rule 71.3.E.1. The exemption states that the provisions of this rule shall not apply to any equipment that transfers an ROC liquid with a modified Reid vapor pressure of less than 0.5 psia. This attachment does not apply to the transfer of gasoline, or to the transfer of ROC liquids via pipeline.

A loading facility is defined as any aggregation or combination of organic liquid loading equipment which is located so that all the organic liquid loading outlets for such aggregation or combination of loading equipment can be encompassed within any circle of 300 feet in diameter.

Conditions:

1. Pursuant to Rule 71.3.E.1, the loading facility shall not be used to transfer an ROC liquid with a modified Reid vapor pressure of greater than or equal to 0.5 psia.
2. Permittee shall annually determine the liquid vapor pressure of all products at the loading facility in order to certify that the modified Reid vapor pressure is less than 0.5 psia. Records of the vapor pressure determinations shall be maintained at the facility and submitted to the District with the annual compliance certification.
3. Pursuant to Rule 71.3.G.1 the method for determining the vapor pressure shall be as follows:
 - a. For petroleum products, the modified Reid vapor pressure shall be measured at the product transfer temperature using ASTM Method No. D-323-82 Volume 5.01, Section 5.
 - b. For an organic liquid, if the liquid is listed in Attachment 1 of Rule 71.2, and if the transfer temperature of the liquid does not exceed the maximum temperature listed corresponding to 0.5 psia, then it shall be deemed exempt from Rule 71.3 requirements.

**Ventura County Air Pollution Control District
Rule 74.9.D.3 Applicable Requirements
Emergency Standby Stationary Internal Combustion Engines
Operated During Either an Emergency or Maintenance Operation**

Rule 74.9, "Stationary Internal Combustion Engines"

Adopted 11/08/05, Federally-Enforceable

Applicability:

This attachment applies to emergency standby stationary internal combustion engines rated at 50 or more horsepower, not subject to the provisions of APCD Rule 74.16, "Oilfield Drilling Operations," and operated during an emergency or maintenance operation. Maintenance operation is limited to 50 hours per calendar year. Pursuant to Rule 74.9.D.3, emergency standby stationary internal combustion engines operated during an emergency or during maintenance operation of no more than 50 hours per calendar year are exempt from all provisions of Rule 74.9.

As detailed in Rule 74.9.I.2 an emergency standby engine is defined as an internal combustion engine used only when normal power line or natural gas service fails, or for the emergency pumping of water for either fire protection or flood relief. An emergency standby engine may not be operated to supplement a primary power source when the load capacity or rating of the primary power source has been either reached or exceeded.

Conditions:

1. Pursuant to Section D.3 of Rule 74.9, an applicable emergency standby stationary internal combustion engine shall only be operated during an emergency or during maintenance operation of not more than 50 hours per calendar year.

Pursuant to Section I.5 of Rule 74.9, a maintenance operation is defined as the use of an emergency standby engine and fuel system during testing, repair and routine maintenance to verify its readiness for emergency standby use.

2. Pursuant to Section D.3 of Rule 74.9, each emergency standby engine shall be equipped with an operating, non-resettable, elapsed hour meter.
3. Pursuant to Section F.1 of Rule 74.9, the Annual Compliance Certification shall include the following records for each emergency standby engine: Engine manufacturer, model number, operator identification number, and location.

4. Pursuant to Section F.2 of Rule 74.9, the annual engine hours of maintenance operation shall be reported annually. A report shall be provided to the District after every calendar year by February 15.

M:\TITLEV\Attachments updated\749N7 (11-08-05).docx

Ventura County Air Pollution Control District
Rule 74.15.B.1 Applicable Requirements
Boilers, Heater Treaters, Steam Generators, and Process Heaters
NO_x and CO Emission Limits
Annual Heat Input \geq 9,000 MMBTU

Rule 74.15, "Boilers, Steam Generators, and Process Heaters"
Adopted 11/08/94, Federally-Enforceable

Applicability:

This attachment applies to boilers, heater treaters, steam generators and process heaters with a maximum heat input rating of greater than or equal to 5 MMBTU/Hr that have operated with an annual heat input rate of greater than or equal to 9,000 MMBTU during any twelve (12) calendar month rolling period. This attachment also applies to any unit operated with an annual heat input rate of less than 9,000 MMBTU that is equipped with low NO_x burners or other such equipment to comply with the NO_x and CO requirements of Rule 74.15.B.1. A heat input of 9,000 MMBTU is equivalent to 90,000 therms and equivalent to 8.57 million cubic feet of natural gas at a higher heating value of 1,050 BTU/cf.

A boiler, steam generator or process heater is any external combustion equipment fired with liquid and/or gaseous fuel. A boiler or a steam generator is further defined as equipment used to produce steam or to heat water. Boiler or steam generator does not include any unfired waste heat recovery boiler that is used to recover sensible heat from the exhaust of any combustion equipment. A process heater is further defined as equipment that transfers heat from combustion gases to water or process streams. Process heater does not include any kiln or oven used for drying, baking, cooking, calcinating or vitrifying, or any fuel-fired degreasing or metal finishing equipment. Annual heat input is defined as the actual amount of heat released by fuels burned in a unit during a twelve (12) calendar month rolling period, based on the higher heating value of the fuel. The annual heat input shall be calculated as the sum of the previous 12 monthly fuel use rates multiplied by the higher heating value of the fuel.

Conditions:

1. Pursuant to Rule 74.15.B.1, emissions from an applicable emission unit shall not exceed the following limits:
 - a. Oxides of Nitrogen (NO_x expressed as NO₂): 40 ppmvd
 - b. Carbon Monoxide (CO): 400 ppmvd

These limits shall be referenced at three (3) percent volume stack gas oxygen on a dry basis averaged over 15 consecutive minutes. Compliance with this condition shall be verified every 24 months by source testing.

2. Pursuant to Rule 74.15.B.1, an applicable emission unit shall be source tested not less than once every 24 months (biennially) utilizing the following methods as detailed in Rule 74.15.E:

- | | | |
|----|------------------|----------------|
| a. | NOx | ARB Method 100 |
| b. | CO | ARB Method 100 |
| c. | Stack Gas Oxygen | ARB Method 100 |

Pursuant to Rule 74.15.E.2, emission tests shall be conducted on units in "as-found" operating condition. However, no emission test for Rule 74.15 shall be conducted during start-up, shutdown or under breakdown conditions. Prior to conducting a biennial emissions test, permittee shall notify the District Compliance Division. Written notification, and a source test protocol subject to District approval, shall be received no less than 15 calendar days prior to the test. The emissions test report and results shall be submitted to the District Compliance Division within 45 days after the test.

3. Pursuant to Rule 74.15.C.2, the emission limits of Rule 74.15.B.1 shall not apply to any unit operated on alternate fuel under the following conditions:

- a. Alternate fuel is required due to the curtailment of natural gas service to the individual unit by the natural gas supplier. Alternate fuel use in this case shall not exceed the period of natural gas curtailment.
- b. Alternate fuel use is required to maintain the alternate fuel system. Alternate fuel use in this case shall not exceed 50 hours per year.

4. Pursuant to Rule 74.15.C.4, the emission limits of Rule 74.15.B.1 shall not apply during the cold startup of an applicable unit. For units with a rated heat input capacity of equal to, or greater than, one hundred (100) million BTUs per hour, the duration of this exemption shall not exceed three (3) hours. For units with a rated heat input capacity of less than one hundred (100) million BTUs per hour, the duration of this exemption shall not exceed one (1) hour.

5. Permittee shall record and maintain the following information:

- a. Daily records of alternate fuel consumption as required by Rule 74.15.D.3. Each record shall include the type of fuel, the quantity of fuel, and the duration of the occurrence; and
- b. The biennial source test report.

This information shall be submitted to the District upon request.

6. If the emission unit is equipped with an external flue gas recirculation (FGR) system for the control of nitrogen oxides, permittee shall also comply with the FGR monitoring and recordkeeping requirements in the Permit Specific Conditions (Attachments) presented in Section No. 7 of this permit.

M:\TITLEV\Attachments updated\7415N1.DOC

Ventura County Air Pollution Control District
Rule 74.15.1.B.1 Applicable Requirements
Boilers, Heater Treaters, Steam Generators, and Process Heaters
Heat Inputs \geq 1 MMBTU/hr and $<$ 5 MMBTU/hr
NO_x and CO Emission Limits
Annual Heat Input \geq 1,800 MMBTU

Rule 74.15.1, "Boilers, Steam Generators, and Process Heaters"
Adopted 06/23/15, Federally-Enforceable

Applicability:

This attachment applies to boilers, heater treaters, steam generators and process heaters with a rated heat input capacity equal to or greater than 1 MMBTU/Hr and less than 5 MMBTU/Hr that have operated with an annual heat input rate of greater than or equal to 1,800 MMBTU during any twelve (12) calendar month rolling period. This attachment also applies to any unit operated with an annual heat input rate of less than 1,800 MMBTU that is equipped with low NO_x burners or other such equipment to comply with the NO_x and CO requirements of Rule 74.15.1.B.1. A heat input of 1,800 MMBTU is equivalent to 18,000 therms and equivalent to 1.71 million cubic feet of natural gas at a higher heating value of 1,050 BTU/cf. This attachment specifically applies to units installed prior to January 1, 2013 for units with a heat input capacity of equal to or greater than 1 MMBTU/hr and less than or equal to 2 MMBTU/hr; and installed prior to January 1, 2016 for units with a heat input capacity of greater than 2 MMBTU/hr and less than 5 MMBTU/hr. These units have a Rule 74.15.1.B.1 limit of 30 ppmvd NO_x at 3% oxygen.

A boiler, steam generator or process heater is any external combustion equipment fired with liquid and/or gaseous fuel. A boiler or a steam generator is further defined as equipment used to produce steam or to heat water. Boiler or steam generator does not include any unfired waste heat recovery boiler that is used to recover sensible heat from the exhaust of any combustion equipment. A process heater is further defined as equipment that transfers heat from combustion gases to water or process streams. A process heater does not include any of the following combustion sources: kiln, oven, open heated tank, dehydrator, dryer, crematory, incinerator, calciner, cooker, roaster, furnace; unfired waste heat recovery heater that is used to recover sensible heat from the exhaust of any combustion equipment; fuel-fired degreasing or metal finishing equipment including parts washers and metal heat treating or metal furnaces; afterburner, vapor incinerator, thermal or catalytic oxidizers used as an emission control device; glass melting furnace; tenter frame, fabric, or carpet dryer. Annual heat input is defined as the actual amount of heat released by fuels burned in a unit during a twelve (12) calendar month rolling period, based on the higher heating value of the fuel. The annual heat input shall be calculated as the sum of the previous 12 monthly fuel use rates multiplied by the higher heating value of the fuel.

Conditions:

1. Pursuant to Rule 74.15.1.B.1, emissions from an applicable emission unit shall not exceed the following limits:
 - a. Oxides of Nitrogen (NO_x expressed as NO₂): 30 ppmvd
 - b. Carbon Monoxide (CO): 400 ppmvd

These limits shall be referenced at three (3) percent volume stack gas oxygen on a dry basis averaged over 15 consecutive minutes. Compliance with this condition shall be verified by source testing as detailed below.

2. Source testing:
 - a. Pursuant to Rule 74.15.1.B.4.a, units with a rated heat input capacity greater than 2 MMBTU/hr shall be source tested for compliance not less than once every 24 months.
 - b. Pursuant to Rule 74.15.1.B.4.c, units with a rated heat input capacity of less than or equal to 2 MMBTU/hr shall be source tested for compliance not less than once every 48 months.
3. Required source testing shall utilize the following methods as detailed in Rule 74.15.1.E:
 - a. NO_x ARB Method 100
 - b. CO ARB Method 100
 - c. Stack Gas Oxygen ARB Method 100

Pursuant to Rule 74.15.1.E.2, emission tests shall be conducted on units in "As-found" operating condition. Prior to conducting a required emissions test, permittee shall notify the District Compliance Division. Written notification shall be received no less than 15 calendar days prior to the test. The emissions test report and results shall be submitted to the District Compliance Division within 45 days after the test.

4. Pursuant to Rule 74.15.1.B.4.d, an annual screening analysis of NO_x and CO emissions shall be performed on the unit. The screening analysis is not required if the source testing required by Rule 74.15.1.B.4.a or 74.15.1.B.4.c (Condition No. 2) is required that year. The permittee shall notify the VCAPCD Compliance Division by telephone, fax, or email 24 hours prior to any screening analysis. Pursuant to Rule 74.15.1.D.3, the permittee shall submit a report to the District Compliance Division within 45 days after each screening analysis.
5. Pursuant to Rule 74.15.1.C.1, the emission limits of Rule 74.15.1.B.1 shall not apply to any unit operated on alternate fuel under the following conditions:

- a. Alternate fuel is required due to curtailment of natural gas service to the individual unit by the natural gas supplier. Alternate fuel use in this case shall not exceed the period of natural gas curtailment.
 - b. Alternate fuel use is required to maintain the alternate fuel system. Alternate fuel use in this case shall not exceed 50 hours per year.
6. The permittee shall record and maintain the following information:
- a. Daily records of alternate fuel consumption as required by Rule 74.15.1.D.4. Each record shall include the type of fuel, the quantity of fuel, and the duration of the occurrence; and
 - b. Required source test reports.
 - c. Annual screening analysis logs and reports as required by Rule 74.15.1.D.3.

This information shall be submitted to the District upon request.

Ventura County Air Pollution Control District
Rule 74.15.1 Applicable Requirements
Boilers, Heater Treaters, Steam Generators, and Process Heaters
Equipment Currently Shut Down and Not Operating

Rule 74.15.1, "Boilers, Steam Generators, and Process Heaters"
Adopted 06/23/15, Federally-Enforceable

Applicability:

This attachment applies to boilers, heater treaters, steam generators and process heaters with a rated heat capacity equal to or greater than 1 MMBTU/Hr and less than 5 MMBTU/Hr that are currently shut down and not operating.

A boiler, steam generator or process heater is any external combustion equipment fired with liquid and/or gaseous fuel. A boiler or a steam generator is further defined as equipment used to produce steam or to heat water. Boiler or steam generator does not include any unfired waste heat recovery boiler that is used to recover sensible heat from the exhaust of any combustion equipment. A process heater is further defined as equipment that transfers heat from combustion gases to water or process streams. A process heater does not include any of the following combustion sources: kiln, oven, open heated tank, dehydrator, dryer, crematory, incinerator, calciner, cooker, roaster, furnace; unfired waste heat recovery heater that is used to recover sensible heat from the exhaust of any combustion equipment; fuel-fired degreasing or metal finishing equipment including parts washers and metal heat treating or metal furnaces; afterburner, vapor incinerator, thermal or catalytic oxidizers used as an emission control device; glass melting furnace; tenter frame, fabric, or carpet dryer. Annual heat input is defined as the actual amount of heat released by fuels burned in a unit during a twelve (12) calendar month rolling period, based on the higher heating value of the fuel. The annual heat input shall be calculated as the sum of the previous 12 monthly fuel use rates multiplied by the higher heating value of the fuel.

Conditions:

1. Prior to operating an applicable emission unit, permittee shall:
 - a. Notify the District Compliance Division; and
 - b. Install a dedicated fuel meter pursuant to Rule 74.15.1.D.1. The meter shall be accurate to ± 1 percent, as certified by the manufacturer in writing.

2. Any applicable emission unit operated with an annual heat input rate of equal to or greater than 300 MMBTU and less than 1800 MMBTU shall comply with the tuning requirements of Rule 74.15.1.B.3.

3. Prior to operating any applicable emission unit with an annual heat input rate of equal to or greater than 1800 MMBTU, the permittee shall demonstrate by source testing, using ARB Method 100 as detailed in Rule 74.15.1.E, that the unit complies with the required nitrogen oxide (NO_x) and carbon monoxide (CO) limits of either Rule 74.15.1.B.1 or Rule 74.15.1.B.2, as applicable. If the unit requires physical modifications in order to meet the emission limits, permittee shall apply for and receive an Authority to Construct and Permit to Operate for the modification.
5. The permittee shall annually certify that the subject equipment is shut down and not operating.
6. Upon operating an applicable emission unit, totalizing fuel meter records shall be compiled monthly into a rolling twelve (12) calendar month report. These records shall be submitted to the District upon request.

M:\TITLEV\Attachments updated\74151N4 (03-01-19).docx

**Ventura County Air Pollution Control District
California Airborne Toxic Control Measure For
Stationary Compression Ignition Engines
In-Use Emergency Fire Pump Assembly Engines**

**Section 93115, Title 17, California Code of Regulations, Airborne Toxic Control Measure
for Stationary Compression Ignition (CI) Engines
Effective 05/19/11**

The District is required to implement and enforce the state ATCM. The ATCM is not federally-enforceable.

Applicability:

This attachment describes the requirements of California Airborne Toxic Control Measure (ATCM) For Stationary Compression Ignition (CI) Engines that apply to in-use stationary diesel-fueled CI engines that drive fire pump assemblies. Section 93115.3(n) of the ATCM exempts such engines from the emission standards for stationary emergency standby diesel-fueled CI engines as listed in Section 93115.6(b)(3) of the ATCM. The exempt engines must only be operated the number of hours necessary to comply the testing requirements of National Fire Protection Association (NFPA) 25 – “Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems,” 2002 edition. An “in-use” engine is an engine that was installed at a facility prior to January 1, 2005. Pursuant to Section 93115.4(a)(8) CARB Diesel Fuel means any diesel fuel that meets the specifications of vehicular diesel fuel, as defined in title 13, CCR, sections 2281 and 2282. The Verification Procedure is defined in Section 93115.4(a)(78).

Conditions:

1. Pursuant to subsection 93115.5(a), as of January 1, 2006, the permittee shall not fuel the engine with any fuel unless the fuel is one of the following:
 - a. CARB Diesel Fuel, or
 - b. An alternative diesel fuel that is:
 - 1) biodiesel;
 - 2) a biodiesel blend that does not meet the definition of CARB diesel Fuel
 - 3) a Fischer-Tropsch fuel; or
 - 4) an emulsion of water in diesel fuel; or
 - c. any alternative diesel fuel that is not identified in section 93115.5(a)(2) and meets the requirements of the Verification Procedure; or
 - d. an alternative fuel; or
 - e. CARB Diesel Fuel used with fuel additives that meets the requirements of the Verification Procedure; or

- f. any combination of the above.
- 2. Pursuant to subsection 93115.10(f)(1)(E), the permittee shall keep a monthly log of each engine's hours of operation to comply with the requirements of NFPA 25.
- 3. Pursuant to subsection 93115.5(f)(1)(H), the permittee shall document fuel use in the engines. For engines operated exclusively on CARB Diesel Fuel, the owner or operator shall document the use of CARB Diesel Fuel through the retention of fuel purchase records indicating that the only fuel purchased for supply to an emergency standby engine was CARB Diesel Fuel; or for engines operated on any fuel other than CARB Diesel Fuel, the fuel records demonstrating that the only fuel purchased and added to an emergency standby engine or engines, or to any fuel tank directly attached to an emergency standby engine or engines, meets the requirements of section 93115.5(b).

M:\TITLEV\Attachments updated\ATCM Engine N1 (05-19-11).docx

**Ventura County Air Pollution Control District
National Emission Standards for Hazardous Air Pollutants
For Stationary Reciprocating Internal Combustion Engines
Existing Emergency Diesel Engines at an Area Source of HAPs**

**40 CFR Part 63, Subpart ZZZZ, “National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines” (RICE MACT)
RICE MACT Last Revised 01/30/13**

Applicability:

The NESHAP for Stationary Reciprocating Internal Combustion Engines is applicable to all stationary reciprocating internal combustion engines (RICE) at both major and area sources of hazardous air pollutants. The NESHAP is applicable to both compression ignition (CI – diesel) engines and spark ignition (SI – natural gas, landfill gas, gasoline, propane, etc.) engines. The specific conditions below are for existing emergency diesel engines at an area source. An engine is defined as “existing” if it was constructed before June 12, 2006. A stationary source is defined as an “area source” if it is not a major source of HAP (Hazardous Air Pollutants) emissions; meaning the stationary source does not emit or have the potential to emit any single HAP at a rate of 10 tons or more per year or any combination of HAP at a rate of 25 tons or more per year.

Pursuant to Section 63.6640(f) and Section 63.6675, an “emergency engine” is any engine whose operation is limited to emergency situations and required testing and maintenance. An emergency can be the loss of grid power or the stationary source’s own power production. An emergency engine may also participate in an emergency demand response program under limited circumstances. Stationary RICE used for peak shaving or as part of a financial arrangement to supply power into the grid, or as a part of a non-emergency demand response program are not considered emergency stationary RICE.

For more up-to-date information regarding RICE NESHAP standards, please refer to the following link: <https://www.epa.gov/stationary-engines/national-emission-standards-hazardous-air-pollutants-reciprocating-internal-0>

Conditions:

1. Pursuant to Section 63.6603(a), Table 2d, the permittee shall comply with the following operating requirements:
 - a. Change oil and filter every 500 hours of operation or annually, whichever comes first. An oil analysis program as described in Section 63.6625(i) can be utilized in order to extend the specified oil change requirement.
 - b. Inspect air cleaner every 1,000 hours of operation or annually, whichever comes

first, and replace as necessary.

- c. Inspect all hoses and belts every 500 hours of operation or annually, whichever comes first, and replace as necessary.

Pursuant to Table 2d, if an emergency RICE is operating during an emergency and it is not possible to perform the above maintenance or if performing the maintenance would otherwise pose an unacceptable risk under federal, state, or local law, the maintenance can be delayed and should be performed as soon as practicable after the emergency has ended or the unacceptable risk has abated. All such maintenance delays shall be reported to the APCD Compliance Division.

2. Pursuant to Section 63.6625(e) and 63.6640(a), Table 6, the permittee shall operate and maintain the stationary RICE according to the manufacturer's emission-related written instructions or develop your own plan which must provide to the extent practicable for the maintenance and operation of the engine in a manner consistent with good air pollution control practice for minimizing emissions.
3. Pursuant to Section 63.6625(f), the RICE shall be equipped with a non-resettable hour meter.
4. Pursuant to Section 63.6625(h), the permittee shall minimize the engine's time spent at idle during startup and minimize the engine's startup time to a period needed for appropriate and safe loading of the engine, not to exceed 30 minutes.
5. Pursuant to Sections 63.6640(f) and 63.6675, the permittee shall operate the emergency RICE in compliance with the following requirements:
 - a. There is no time limit on the use of emergency stationary RICE in emergency situations. An emergency can be the loss of grid power or the stationary source's own power production.
 - b. The use of the engine is limited to 100 hours per calendar year for maintenance checks and readiness testing, emergency demand response, 5% or greater voltage or frequency deviation situations, and up to 50 hours per year for non-emergency situations as detailed in Section 63.6640(f)(4). The 50 hours are to be counted in the 100 hours limit.
 - c. The emergency stationary RICE may be operated up to 50 hours per calendar year in non-emergency situations. The 50 hours of operation in non-emergency situations are counted as part of the 100 hours per calendar year for maintenance and testing and emergency demand response provided above. The 50 hours per year for non-emergency situations cannot be used for peak shaving or non-

emergency demand response to generate income for a facility. The 50 hours per year for non-emergency situations can be used to supply power as part of a financial agreement with another entity if all of the requirements of Section 63.6640(f)(4)(ii)(A–E) are met. The 50 hours per year limit is to be counted towards the 100 hours per year limit.

6. Pursuant to Sections 63.6655(e) and 63.6655(f), the permittee shall maintain the following records:
 - a. Records of maintenance conducted on the stationary emergency RICE.
 - b. Records of the hours of operation of the engine that is recorded through the non-resettable hour meter. The permittee must document how many hours are spent for emergency operation, including what classified the operation as emergency, and how many hours are spent for non-emergency operation.
7. If the engine is contractually obligated to be available for more than 15 hours per year for emergency demand response, 5% or greater voltage or frequency deviation situations, or for non-emergency situations as detailed in Section 63.6640(f)(4)(ii) the engine must use a diesel fuel that meets the requirements in 40 CFR 80.510(b) for non-road diesel fuel. This fuel is commonly known as ultra low sulfur diesel or ULSD. Any diesel fuel purchased (or otherwise obtained) prior to January 1, 2015 may be used until depleted. (Section 63.6604(b))
8. If the engine is contractually obligated to be available for more than 15 hours per year for emergency demand response, 5% or greater voltage or frequency deviation situations, or for non-emergency situations as detailed in Section 63.6640(f)(4)(ii) the permittee is required to compile and submit a report as required by Section 63.6650(h). This report includes, but is not limited to, location information, engine information, hours of operation, and fuel requirement deviations. The first annual report must cover calendar year 2015 and must be submitted no later than March 31, 2016. Subsequent annual reports for each calendar year must be submitted no later than March 31 of the following calendar year. As required by Section 63.6650(h)(3), the annual report must be submitted electronically via EPA's Central Data Exchange (CDX). (Section 63.6650(h))
9. On an annual basis, the permittee shall certify that all engines at this stationary source are operating in compliance with 40 CFR Part 63, Subpart ZZZZ, "National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Engines" (RICE MACT).

**Ventura County Air Pollution Control District
National Emission Standards for Hazardous Air Pollutants
For Stationary Reciprocating Internal Combustion Engines
Existing Emergency Spark Ignited Engines**

40 CFR Part 63, Subpart ZZZZ, “National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines” (RICE MACT)

Applicability:

The NESHAP for Stationary Reciprocating Internal Combustion Engines is applicable to all stationary reciprocating internal combustion engines (RICE) at both major and area sources of hazardous air pollutants. The NESHAP is applicable to both compression ignition (CI – diesel) engines and spark ignition (SI – natural gas, landfill gas, gasoline, propane, etc.) engines. The specific conditions below are for existing emergency spark ignited engines at an area source. An engine is defined as “existing” if it was constructed before June 12, 2006. A stationary source is defined as an “area source” if it is not a major source of HAP (Hazardous Air Pollutants) emissions; meaning the stationary source does not emit or have the potential to emit any single HAP at a rate of 10 tons or more per year or any combination of HAP at a rate of 25 tons or more per year.

Pursuant to Section 63.6640(f) and Section 63.6675, an “emergency engine” is any engine whose operation is limited to emergency situations and required testing and maintenance. An emergency can be the loss of grid power or the stationary source’s own power production. An emergency engine may also participate in an emergency demand response program under limited circumstances. Stationary RICE used for peak shaving or as part of a financial arrangement to supply power into the grid, or as a part of a non-emergency demand response program are not considered emergency stationary RICE.

Pursuant to Section 63.6595(a)(1), the permittee must comply with the applicable operating requirements on and after May 3, 2013.

Conditions:

1. Pursuant to Section 63.6603(a), Table 2d, the permittee shall comply with the following operating requirements:
 - a. Change oil and filter every 500 hours of operation or annually, whichever comes first. An oil analysis program as described in Section 63.6625(i) can be utilized in order to extend the specified oil change requirement.
 - b. Inspect spark plugs every 1,000 hours of operation or annually, whichever comes first, and replace as necessary.

- c. Inspect all hoses and belts every 500 hours of operation or annually, whichever comes first, and replace as necessary.

Pursuant to Table 2d, if an emergency RICE is operating during an emergency and it is not possible to perform the above maintenance or if performing the maintenance would otherwise pose an unacceptable risk under federal, state, or local law, the maintenance can be delayed and should be performed as soon as practicable after the emergency has ended or the unacceptable risk has abated. All such maintenance delays shall be reported to the APCD Compliance Division.

2. Pursuant to Section 63.6625(e) and 63.6640(a), Table 6, the permittee shall operate and maintain the stationary RICE according to the manufacturer's emission-related written instructions or develop your own plan which must provide to the extent practicable for the maintenance and operation of the engine in a manner consistent with good air pollution control practice for minimizing emissions.
3. Pursuant to Section 63.6625(f), the RICE shall be equipped with a non-resettable hour meter.
4. Pursuant to Section 63.6625(h), the permittee shall minimize the engine's time spent at idle during startup and minimize the engine's startup time to a period needed for appropriate and safe loading of the engine, not to exceed 30 minutes.
5. Pursuant to Sections 63.6640(f) and 63.6675, the permittee shall operate the emergency RICE in compliance with the following requirements:
 - a. There is no time limit on the use of emergency stationary RICE in emergency situations. An emergency can be the loss of grid power or the stationary source's own power production.
 - b. The use of the engine is limited to 100 hours per calendar year for maintenance checks and readiness testing, emergency demand response, 5% or greater voltage or frequency deviation situations, and up to 50 hours per year for non-emergency situations as detailed in Section 63.6640(f)(4). The 50 hours are to be counted in the 100 hours limit.
 - c. The emergency stationary RICE may be operated up to 50 hours per calendar year for peak shaving as part of a financial agreement to supply power into the grid, or as part of a non-emergency demand response program, until May 3, 2014. After May 3, 2014, the 50 hours per year for non-emergency situations can be used to supply power as part of a financial agreement if all of the requirements of Section

63.6640(f)(4)(ii) are met. The 50 hours per year limit is to be counted towards the 100 hours per year limit.

6. Pursuant to Sections 63.6655(e) and 63.6655(f), the permittee shall maintain the following records:
 - a. Records of maintenance conducted on the stationary emergency RICE.
 - b. Records of the hours of operation of the engine that is recorded through the non-resettable hour meter. The permittee must document how many hours are spent for emergency operation, including what classified the operation as emergency, and how many hours are spent for non-emergency operation.
7. If the engine site rating exceeds 100 brake HP and operates or is contractually obligated to be available for more than 15 hours per year for purposes specified in Section 63.6640(f)(2)(ii) and (iii) or that operates for the purposes specified in Section 63.6640(f)(4)(ii) the permittee is required to compile and submit a report as required by Section 63.6650(h). The annual report must be submitted no later than March 31 of each year. (Section 63.6650(h))
8. On an annual basis, the permittee shall certify that all engines at this stationary source are operating in compliance with 40 CFR Part 63, Subpart ZZZZ, "National Emission Standards for Hazardous Air Pollutants for Stationary Reciprocating Engines" (RICE MACT).

M:\TITLEV\Attachments updated\CFR63ZZZN9_existing emergency SI area HAP.docx

8. PERMIT SPECIFIC CONDITIONS (ATTACHMENTS)

As discussed in Section No. 2, “Permitted Equipment and Applicable Requirements Table”, the emissions units at this stationary source listed in the table have requirements that are specifically applicable to them. The applicable requirements are primarily based on Rule 26, “New Source Review” requirements (e.g., BACT and offset requirements), or Rule 29, “Conditions on Permits” requirements (e.g., throughput recordkeeping requirements, specific requirements that limit emissions, etc.). These requirements are in addition to the specific applicable requirements listed in Section No. 7.

In this section of the permit, the permit conditions that are associated with each specific applicable requirement are listed in an individual attachment. The attachment is identified with the label “Attachment PO (Title V Permit No.) PC#” in the lower left corner. Each attachment has an applicability section that describes how and why this attachment applies to the specific emissions unit. The attachment may apply to one or more of the emissions units listed in the Permitted Equipment and Applicable Requirements Table in Section No. 2.

**Ventura County Air Pollution Control District
Additional Permit Requirements
Permit No. 00012**

Rule 26, "New Source Review"

Rule 29, "Conditions on Permits"

Conditions applied pursuant to Rule 26 are federally enforceable and conditions applied pursuant to Rule 29 are District enforceable only.

Applicability:

This attachment applies to this stationary source. These requirements are in addition to any other specific or general requirements referenced in this permit.

Conditions:

1. In order to comply with the throughput and consumption limits of this permit, the permittee shall maintain monthly records of throughput and consumption as detailed in Section No. 3, "Permitted Throughput and Consumption Limit Table", of this permit. The monthly records shall be summed for the previous 12 months. Throughput or consumption totals for any of these 12 calendar month rolling periods in excess of the specified limit shall be considered a violation of this permit. This is a general throughput and consumption recordkeeping condition and applies unless another throughput and consumption recordkeeping condition appears in this section of the permit. (Rules 26 and 29)
2. The permitted emissions authorized by this permit are based in part on the fugitive emissions from 70 oil wells. An Authority to Construct is required to be obtained from the District prior to drilling a new oil well. Emission offsets must also be provided with the submittal of any application to increase the number of wells beyond 70 wells. (Rule 29)
3. The following wells shall be shall be free flowing, operated on gas lift, or operated with electric motor driven artificial lift equipment:

Chase C8, Chase E9, Chase D11, Chase F12, TransAmerica B5, TransAmerica C2, TransAmerica D10

This condition is applied as Best Available Control Technology. (Rule 26)
4. Pursuant to Rule 23.F.7, the use of solvents, in addition to the use of coatings, adhesives, lubricants, and sealants, for facility and building maintenance and repair is exempt from

permit. However, the use of such materials by contractors for the maintenance and repair of process and industrial equipment is not exempt from permit pursuant to Rule 23.F.7, unless the material is exempted under another specific section of Rule 23. Pursuant to Rule 23.F.6, the use of non-refillable aerosol cans is exempt from permit. Pursuant to Rule 23.F.10, the use of cleaning agents certified by the SCAQMD as Clean Air Solvents (Rule 23.F.10.a) and the use of cleaning agents that contain no more than 25 grams per liter of ROC as used or applied, and no more than 5 percent by weight combined of methylene chloride, perchloroethylene, trichloroethylene, 1,1,1-trichloroethane, carbon tetrachloride, and chloroform (Rule 23.F.10.b), is also exempt from permit. This permit does not limit the usage of acetone. Acetone is exempt from permit and record keeping requirements, as it is not defined as a reactive organic compound.

In order to substantiate the solvent use exemptions listed above, the permittee shall maintain a list of all exempt solvents used at the stationary source and a reference to the specific permit exemption status.

(Rule 29)

M:\TITLEV\TV Permits\PO0012\Permit V\PC1 rev-245,331.docx

**Ventura County Air Pollution Control District
Additional Permit Requirements
Nitrite Solution Vessels**

**Rule 29, "Conditions on Permits"
Adopted 03/14/06, District Enforceable Only**

**Rule 64, "Sulfur Content of Fuels"
Adopted 04/13/99, Federally-Enforceable**

Applicability:

This attachment applies to the nitrite solution vessels or nitrite solution buffer vessels located at this facility. These vessels are used to sweeten, or remove hydrogen sulfide from, gas produced from wells at this facility. These requirements are in addition to any other specific or general requirements referenced in this permit.

Conditions:

1. All produced gas and casing gas shall be processed through the nitrite solution produced gas sweetening system. (Rule 64)
2. The produced gas and casing gas shall not be burned as fuel in the boilers, steam generators or process heaters if the gas contains sulfur compounds, calculated as hydrogen sulfide at standard conditions, in excess of 236 ppmv, or the equivalent 15 grains per 100 cubic feet. (Rule 29)
3. On a weekly basis, permittee shall test the hydrogen sulfide content of the gases downstream of the nitrite solution vessels or nitrite solution buffer vessels located throughout the facility. The tests shall be performed using detector tubes that measure hydrogen sulfide. Permittee shall maintain this test information and make it available to the District upon request. (Rule 64)
4. Permittee shall analyze the sulfur content of this fuel gas on an annual basis using South Coast AQMD Method 307-94 - Determination of Sulfur in a Gaseous Matrix. This annual fuel gas analysis shall satisfy the requirements of Permit Condition No. 2 above, as well as the requirements of Rule 64.B.1. Records of the test shall be maintained at the facility and the test results shall be provided to the District with the annual compliance certification. (Rule 64)

**Ventura County Air Pollution Control District
Additional Permit Requirements
20 MMBTU/Hr Erie City Boiler**

Rule 26, "New Source Review"

**Rule 74.15, "Boilers, Steam Generators, and Process Heaters"
Adopted 11/08/94, Federally-Enforceable**

Conditions applied pursuant to Rule 26 are federally enforceable.

Applicability:

This attachment applies to the 20 MMBTU/Hr Erie City boiler located at this facility. These requirements are in addition to any other specific or general requirements referenced in this permit.

Conditions:

1. The stack outlet concentrations of oxides of nitrogen (NO_x measured as NO₂) shall not exceed 36 parts per million by volume (ppmv) corrected to 3 percent oxygen. This is a requirement of Rule 26 as detailed in Authority to Construct No. 0012-110. (Rule 26)
2. Permittee shall operate the Erie City boiler at a flue gas recirculation (FGR) rate at or above a valve opening setting of 45%, and an excess oxygen rate between 0.5% and 3.0%. These operating parameters shall be monitored, measured, and recorded on a monthly basis. Any deviation from the minimum FGR valve position of 45% or any deviation from the excess oxygen rate range shall be considered a violation of this condition, unless the permittee can demonstrate compliance with the NO_x emission limits specified in Permit Condition No. 1 above by emission testing pursuant to Rule 74.15. (Rule 26 and Rule 74.15)
3. Permittee shall have the boiler emissions tested no less than once every 24 months and shall maintain the external flue gas recirculation system (FGR) according to the parameters specified in Permit Condition No. 2 above. Additional monitoring, recordkeeping, reporting, and test method requirements for this unit are included in Attachment 74.15N1 in Section No. 7 of this permit. (Rule 26 and Rule 74.15)

M:\TITLEV\TV Permits\PO0012\Permit V\PC3.docx

**Ventura County Air Pollution Control District
Additional Permit Requirements
20 MMBTU/Hr Natco Crude Oil Process Heater**

Rule 26, "New Source Review"

**Rule 74.15, "Boilers, Steam Generators, and Process Heaters"
Adopted 11/08/94, Federally-Enforceable**

Conditions applied pursuant to Rule 26 are federally enforceable.

Applicability:

This attachment applies to the 20 MMBTU/Hr Natco crude oil process heater located at this facility. These requirements are in addition to any other specific or general requirements referenced in this permit.

Conditions:

1. The stack outlet concentrations of oxides of nitrogen (NO_x measured as NO₂) shall not exceed 34 parts per million by volume (ppmv) corrected to 3 percent oxygen. This is a requirement of Rule 26 as detailed in Authority to Construct No. 0012-110. (Rule 26)
2. Permittee shall operate the Natco crude oil process heater at a flue gas recirculation (FGR) rate at or above a valve opening setting of 50%, and an excess oxygen rate between 0.5% and 2.5%. These operating parameters shall be monitored, measured, and recorded on a monthly basis. Any deviation from the minimum FGR valve position of 50% or any deviation from the excess oxygen rate range shall be considered a violation of this condition, unless the permittee can demonstrate compliance with the NO_x emission limits specified in Permit Condition No. 1 above by emission testing pursuant to Rule 74.15. (Rule 26 and Rule 74.15)
3. Permittee shall have the heater emissions tested no less than once every 24 months and shall maintain the external flue gas recirculation system (FGR) according to the parameters specified in Permit Condition No. 2 above. Additional monitoring, recordkeeping, reporting, and test method requirements for this unit are included in Attachment 74.15N1 in Section No. 7 of this permit. (Rule 26 and Rule 74.15)

M:\TITLE\VTV Permits\PO0012\Permit VPC4.docx

**Ventura County Air Pollution Control District
Additional Permit Requirements
20 MMBTU/Hr Steam Generators
(Steam Generator Nos. 0, 1, 2, 4, and 5)**

**Rule 26, “New Source Review”
Federally-Enforceable**

**Rule 29, “Conditions on Permits”
District Enforceable Only**

**Rule 54, “Sulfur Compounds”
Adopted 01/14/14, Federally-Enforceable**

**Rule 64, “Sulfur Content of Fuels”
Adopted 04/13/99, Federally-Enforceable**

**Rule 74.15, “Boilers, Steam Generators, and Process Heaters”
Adopted 11/08/94, Federally-Enforceable**

Applicability:

This attachment applies to the five (5) 20 MMBTU/Hr steam generators in service (Nos. 0, 1, 2, 4, and 5) located at this facility. These requirements are in addition to any other specific or general requirements referenced in this permit.

Conditions:

1. Permittee may burn fuel oil in Steam Generator Nos. 4 and 5 at a maximum rate of 118.2 gallons per hour during periods of mandatory natural gas curtailment by the natural gas supplier. Prior to obtaining approval to burn fuel oil at a higher rate during curtailment, permittee must demonstrate through source testing that these steam generators can meet an oxides of nitrogen (NO_x measured as NO₂) emission limit of 160 parts per million by volume (ppmv) on a dry basis corrected to 3 percent oxygen while burning fuel oil. (Rule 26)

If the permittee desires to burn fuel oil during periods of time other than natural gas curtailment, compliance with the 40 ppmv NO_x and 400 ppmv CO limits of Rule 74.15.B.1 shall be demonstrated prior to such fuel oil burning. (Rule 74.15)

2. PCL Industrial Services, Inc. 20.0 MMBTU/hr Steam Generator (Unit No. 0) Emission Limitations:

- a. Oxides of nitrogen (NO_x measured as NO₂) emissions from the steam generator shall not exceed 5 ppmvd, corrected to 3% oxygen, when burning PUC natural gas.
- b. Oxides of nitrogen (NO_x measured as NO₂) emissions from the steam generator shall not exceed 6 ppmvd, corrected to 3% oxygen, when burning PUC natural gas mixed with produced gas.
- c. Carbon monoxide (CO) emissions from the steam generator shall not exceed 100 ppmvd, corrected to 3% oxygen.

The NO_x limitations are applied as BACT (Best Available Control Technology). The CO limit is applied pursuant to Rule 29, "Conditions On Permits". The NO_x and CO limits are more stringent than the Rule 74.15.B.1 emission limits. In order to demonstrate compliance with these emission limits, the permittee shall have the unit's emissions tested every 24 months. (Rules 26, 29, 74.15)

3. The PCL Industrial Services, Inc. steam generator (Unit No. 0) shall be fired on PUC natural gas or a mixture of PUC natural gas and produced gas that meets a hydrogen sulfide (H₂S) content limit of 20 ppmvd. This condition is applied as BACT (Best Available Control Technology) and Rule 54, "Sulfur Compounds", compliance.

All oilfield gas combustion shall comply with Rule 64, "Sulfur Content of Fuels". The sulfur content of the oilfield gas burned in the steam generator shall be monitored and recorded on an annual basis as required by Section D of Rule 64. The sulfur content of the oilfield gas shall be determined by SCAQMD Method 307-91.

4. The fuel to be burned during commercial operation of Steam Generator Nos. 1 and 2 shall be limited to utility natural gas only. Prior to obtaining approval to burn fuel oil during periods of mandatory natural gas curtailment by the natural gas supplier, permittee must demonstrate through source testing these steam generators can meet an oxides of nitrogen (NO_x measured as NO₂) emission limit of 160 parts per million by volume (ppmv) on a dry basis corrected to 3 percent oxygen while burning fuel oil. (Rule 26)

If the permittee desires to burn fuel oil during periods of time other than natural gas curtailment, compliance with the 40 ppmv NO_x and 400 ppmv CO limits of Rule 74.15.B.1 shall be demonstrated prior to such fuel oil burning. (Rule 74.15)

5. The fuel oil to be burned in Steam Generator Nos. 4 and 5 shall be limited to a sulfur content not to exceed 0.25%, by weight, and a nitrogen content not to exceed 0.25%, by weight. In order to comply with this condition, permittee shall maintain fuel records, or certification from the fuel supplier, documenting the sulfur content and nitrogen content of each fuel delivery. (Rule 29)

6. A totalizing fuel meter shall be installed and dedicated to each steam generator. The meter shall be accurate to \pm one percent and shall be maintained in proper operating condition. (Rule 29)
7. Permittee shall maintain the following flue gas recirculation (FGR) valve opening settings and excess oxygen trim rates:

| Steam Generator No. | Valve Opening Setting | Excess Oxygen Rates |
|---------------------|-----------------------|---------------------|
| 1 | 30 % | 0.5 - 2.5 % |
| 2 | 30 % | 0.5 - 2.5 % |
| 4 | 40 % | 0.5 - 2.5 % |
| 5 | 60 % | 0.5 - 2.5 % |

These operating parameters shall be monitored, measured, and recorded on a monthly basis. Any FGR valve setting less than the FGR valve position setting above, or any deviation from the excess oxygen rates above shall be considered a violation of this condition, unless the permittee can demonstrate compliance with 40 ppmv NO_x by emission testing pursuant to Rule 74.15. (Rule 26 and Rule 74.15)

8. Permittee shall have the steam generators' emissions tested no less than once every 24 months and shall maintain the external flue gas recirculation system (FGR) according to the parameters specified in Permit Condition No. 7 above. Additional monitoring, recordkeeping, reporting, and test method requirements for these units are included in Attachment 74.15N1 in Section No. 7 of this permit.

**Ventura County Air Pollution Control District
Additional Permit Requirements
Asphalt Loading Racks**

Rule 51, "Nuisance"

Adopted 04/13/04, District Enforceable Only

Applicability:

This attachment applies to the asphalt loading racks located at this facility. These requirements are in addition to any other specific or general requirements referenced in this permit.

Conditions:

1. Pursuant to Rule 51, permittee shall operate and maintain a vapor collection and scrubbing system at the asphalt loading racks during all asphalt transfer operations in order to reduce any nuisance created by odor. The vapor collection and filtration system shall minimize displaced vapors from being released into the atmosphere during loading operations by collecting the displaced ROC vapors from the delivery vessel, and passing these vapors through a water scrubber and filtration system prior to release to the atmosphere.
2. The permittee shall annually certify that the vapor collection and scrubbing system is operating properly.

MATITLEV\TV Permits\PO0012\Permit V\PC6 rev-381.docx

**Ventura County Air Pollution Control District
Additional Permit Requirements
Crude Oil and Gas Oil Loading Racks**

**Rule 71.3, "Transfer of Reactive Organic Compound Liquids"
Adopted 06/16/92, Federally-Enforceable**

Rule 26, "New Source Review"

Conditions applied pursuant to Rule 26 are federally enforceable.

Applicability:

This attachment applies to the crude oil loading racks located at the Transamerica Tank C-1 area, Texcon Tank C-2 and C-3 area, and the Main Facility Tank 2005-2006 area. This attachment also applies to gas oil loading rack at the Main Facility Tank 1501-1503 area. These requirements are in addition to any other specific or general requirements referenced in this permit.

Conditions:

1. Regardless of the applicability, requirements, or exemptions of Rule 71.3, permittee shall maintain a bottom-loaded vapor recovery system at the crude oil and gas oil loading racks during all transfer operations. The vapor recovery system shall prevent all displaced vapors during loading from being released into the atmosphere. The vapor recovery system shall be capable of collecting all ROC vapors; and shall have a vapor return system that routes all vapors to a continuously operating boiler firebox for incineration or to a gas pipeline recovery and distribution system. Additional monitoring, recordkeeping, reporting, and test method requirements for these units are included in Attachment 71.3N4 in Section No. 7 of this permit.

This is a requirement of Rule 26 as detailed in Application No. 0011-008 for Emission Reduction Credits as a result of adding vapor recovery to these crude oil and gas oil loading racks.

M:\TITLEV\TV Permits\PO0012\Permit VPC7.docx

**Ventura County Air Pollution Control District
Additional Permit Requirements
Out of Service Emissions Units**

Rule 29, “Conditions on Permits”

Conditions applied pursuant to Rule 29 are District enforceable only.

Applicability:

This attachment applies to any emissions units on permit at this facility that are currently designated as “Out of Service” in Tables 2, 3, and 4 of this permit.

Conditions:

1. Any tank designated as “Out of Service” in Tables 2, 3, and 4 of this permit is shut down, shall not be operated, and shall not contain any liquids.
2. Any combustion unit designated as “Out of Service” in Tables 2, 3, and 4 of this permit is shut down, shall not be operated, and shall not be connected to a fuel source.
3. For emissions units designated as “Out of Service”, compliance with other requirements in this permit, such as source testing, shall be at the discretion of VCAPCD personnel.
4. In order to ensure that compliance with this condition is being maintained, the permittee shall annually certify that an emissions unit designated as “Out of Service” is shut down and not being operated.

M:\TITLEV\TV Permits\PO0012\Permit V\PC8-rev211.docx

**Ventura County Air Pollution Control District
Additional Permit Requirements
Flare**

Rule 26, "New Source Review"

Conditions applied pursuant to Rule 26 are federally enforceable.

**Rule 54, "Sulfur Compounds"
Adopted 01/14/14, Federally Enforceable**

**Rule 71.1, "Crude Oil Production and Separation"
Adopted 06/16/92, Federally Enforceable**

**Rule 71.3, "Transfer of Reactive Organic Compound Liquids"
Adopted 06/16/92, Federally-Enforceable**

Applicability:

This attachment applies to the following flare:

- 1 - 5 MMBTU/hr Flare, PROS, Inc., Model FLTR-1 (trailer mounted), 45 scf/hr Mactronic electric auto ignition pilot, 26' high, Coanda effect technology, equipped with sulfur pre-treatment system

The flare will be used for combustion of gases pursuant to Rules 71.1.B.1.a or 71.1.C.1 by burning excess gas that cannot be combusted in the steam generators or asphalt heaters.

These requirements are in addition to any other specific or general requirements referenced in this permit.

Conditions:

1. There is no annual gas consumption limit at the flare. Permitted emissions for the flare are based on 8,760 hours per year.
2. The flare shall be equipped with a functional, operating automatic ignition system equipped with a gas pilot to ensure combustion disposal of all excess produced or recovered gases. (Rules 71.1 and 71.3)
3. Permittee shall test the flare's ignition system monthly and shall maintain a monthly record of the flare's ignition system tests and maintenance activities, including the test date and operator's initials. (Rules 71.1 and 71.3)

4. The flare shall be smokeless. This condition is applied as BACT. (Rule 26)
5. Flare Oxides of Sulfur (SO_x) Emission Requirements:
 - a. The sulfur content of the gas entering each emergency flare shall not exceed 20 ppmvd, calculated as hydrogen sulfide (H₂S) at standard conditions.
 - b. The flare gas sulfur pre-treatment system shall be operated whenever the flare is operated as necessary to comply with the 20 ppmvd limit above.
 - c. Annual testing for sulfur compounds in the flare gas shall be conducted using H₂S detector tubes, SCAQMD Method 307-91, or EPA Method 16, as applicable.

(Rules 26 and 54)

M:\TITLE\TV Permits\PO0012\Permit V\PC9_rev381.docx

9. GENERAL APPLICABLE REQUIREMENTS (ATTACHMENTS)

The general applicable requirements are broadly applicable requirements that apply and are enforced in the same manner for all subject emissions units or activities. These requirements can normally be adequately addressed in the permit application with minimal or no reference to any specific emissions unit or activity, provided that the scope of the requirement and the manner of its enforcement are clear. Examples of such requirements include those that apply identically to all emissions units at a facility (e.g., source-wide opacity limits), general housekeeping requirements, and requirements that apply identical emissions limits to small units (e.g., process weight requirements).

As detailed in the Title V Permit Reissuance Application, general applicable requirements that apply to this facility were determined. The permit conditions associated with each generally applicable requirement are listed in an individual attachment. The attachment is identified with the label "Attachment (APCD Rule No.) ____" in the lower left corner of each attachment. Each attachment has an applicability section that describes the emissions units to which the attachment applies. Each attachment may apply to one or more of the emissions units listed in the Applicable Requirements Table of Section No. 2. Note that these general applicable requirements may also apply to emissions units not required to be listed in the permit, such as those that are short-term.

Ventura County Air Pollution Control District
Rule 50 Applicable Requirements
Opacity

Rule 50, "Opacity"

Adopted 04/13/04, Federally-Enforceable

Applicability:

This attachment applies to all emissions units at this stationary source.

Conditions:

1. Pursuant to Rule 50.A, permittee shall not discharge into the atmosphere from any single source whatsoever any air contaminants for a period or periods aggregating more than three (3) minutes in any one (1) hour which are as dark or darker in shade as that designated as No. 1 on the Ringelmann Chart, or equivalent to 20% opacity and greater, unless specifically exempted by Rule 50.
2. Permittee shall perform periodic visual inspections to ensure that compliance with Rule 50 is being maintained. A record shall be kept of any occurrence of visible emissions other than uncombined water greater than zero percent for a period or periods aggregating more than three (3) minutes in any one (1) hour. These records shall include the date, time, and identity of emissions unit. If the visible emissions problem cannot be corrected within 24 hours, permittee shall provide verbal notification to the District within the subsequent 24 hours. These visible emissions records shall be maintained at the facility and submitted to the District upon request. Records of zero percent visual emissions are not required.
3. On an annual basis, permittee shall certify that all emissions units at the facility are complying with Rule 50. This annual compliance certification shall include a formal survey identifying the date, time, emissions unit, and verification that there are no visible emissions other than uncombined water greater than zero percent for a period or periods aggregating more than three (3) minutes in any one (1) hour. As an alternative, the annual compliance certification shall include a formal survey identifying the date, time, emissions unit, and verification that there are no visible emissions for a period or periods aggregating more than three (3) minutes in any one (1) hour which are as dark or darker in shade as that designated as No. 1 on the Ringelmann Chart, or equivalent to 20% opacity and greater, as determined by a person certified in reading smoke using EPA Method 9, or any other appropriate test method as approved in writing by the District, the California Air Resources Board, and the U.S. Environmental Protection Agency.
4. Upon District request, opacity shall be determined by a person certified in reading smoke using EPA Method 9 or a certified, calibrated monitoring system.

M:\TITLEV\Attachments updated\50 (03-13-2019).docx

**Ventura County Air Pollution Control District
 Rule 54 Applicable Requirements
 Sulfur Compounds - Sulfur Emissions from
 Combustion Operations at Point of Discharge**

Rule 54, "Sulfur Compounds"
Adopted 01/14/14, Federally Enforceable

Rule 64, "Sulfur Content of Fuels"
Adopted 04/13/99, Federally-Enforceable

Applicability:

This attachment applies to all combustion emissions units at this stationary source that combust gaseous or liquid fuels. This attachment addresses the requirements of Rule 54 for sulfur emissions at the point of discharge. It can be demonstrated that compliance with the fuel sulfur content limits of Rule 64 ensures compliance with the sulfur emission limits of Rule 54.

Conditions:

1. Pursuant to Rule 54.B.1.a, no person shall discharge sulfur compounds from any combustion operation, which would exist as a liquid or gas at standard conditions, in excess of the following limit at the point of discharge:

| | |
|---------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 300 ppm by vol, on a dry basis, as sulfur dioxide (SO ₂), at 3% oxygen | For sources subject to: Rule 74.11, "Natural Gas-Fired Water Heaters" Rule 74.11.1, "Large Water Heaters and Small Boilers" Rule 74.15, "Boilers, Steam Generators, and Process Heaters" Rule 74.15.1, "Boilers, Steam Generators, and Process Heaters" (1 to 5 MMBTUs) |
| 300 ppm by vol, on a dry basis, as sulfur dioxide (SO ₂), at 15% O ₂ | For sources subject to: Rule 74.9, "Stationary Internal Combustion Engines" Rule 74.23, "Stationary Gas Turbines" Flares and all other combustion operations |

2. In order to comply with Rule 54, permittee shall comply with the fuel sulfur content limits of Rule 64. No additional periodic monitoring requirements for Rule 54 are required beyond the periodic monitoring requirements of Rule 64.
3. Upon District request, sulfur compounds at the point of discharge shall be determined by source testing using EPA Test Method 6, 6A, 6C, 8, 15, 16A, 16B, or South Coast AQMD Test Method 307-91 (Determination of Sulfur in a Gaseous Matrix), as appropriate.

M:\TITLEV\Attachments updated\54B1 (03-03-16).docx

Ventura County Air Pollution Control District
Rule 54 Applicable Requirements
Sulfur Compounds - Sulfur Dioxide Concentration at Ground Level

Rule 54, "Sulfur Compounds"
Adopted 01/14/14, Federally Enforceable

Applicability:

This attachment applies to all emissions units at this stationary source that emit sulfur compounds. This attachment addresses the requirements of Rule 54 for sulfur emissions at ground or sea level at or beyond the property line of the stationary source.

Conditions:

1. Pursuant to Rule 54, no person shall discharge sulfur compounds, which would exist as a liquid or gas at standard conditions, as sulfur dioxide which results in average ground or sea level concentrations at any point at or beyond the property line in excess of 0.25 ppmv averaged over any one hour period, or 0.04 ppmv averaged over any 24 hour period.
2. Pursuant to Rule 54.B.2.a, no person shall discharge sulfur compounds, which would exist as a liquid or gas at standard conditions, as sulfur dioxide which results in ground or sea level concentrations at any point at or beyond the property line such that the 1-hour average design value exceeds 0.075 ppm (Vol).
 - a) For purposes of Subsection B.2.a, the design value is derived from the 3-year average of annual 99th percentile daily maximum 1-hour values. At the District's discretion, compliance with the ground or sea level concentration limit in Subsection B.2.a of this rule may be demonstrated using EPA-approved dispersion models or ambient air monitoring. If the District requires ambient air monitoring, the test method(s) listed in Subsection D.2 of this rule must be employed.
 - b) To demonstrate compliance using dispersion modeling, the annual 99th percentile daily maximum at each receptor is determined from model results as follows: for each year of meteorological data modeled, select from each day the maximum hourly modeled SO₂ concentration value and sort all these daily maximum hourly values by descending value. The 99th percentile is the 4th highest value for each modeled year. Calculate the average of the 99th percentile values for three consecutive years of modeling data for each receptor. Compliance is demonstrated if this average value is less than or equal to the design value concentration limit in Subsection B.2.a of this Rule at each receptor.
 - c) Compliance with the limit in subsection B.2.a may also be demonstrated using EPA-approved screen models. Compliance is demonstrated if the 1-hour SO₂

ground or sea level concentration does not exceed 0.075 ppm (Vol) at or beyond the property line.

- d) If ambient air monitoring data is used to demonstrate compliance, the design value must be calculated in accordance with 40 CFR Part 50 Appendix T – Interpretation of the Primary National Ambient Air Quality Standards for Oxides of Sulfur (Sulfur Dioxide).
3. Permittee shall maintain a representative fuel analysis or exhaust analysis, along with modeling data or other demonstration to ensure that compliance with Rule 54 is being maintained. This analysis and compliance demonstration shall be provided to the District upon request.
 4. Upon District request, ground or sea level concentrations of SO₂ shall be determined by Bay Area Air Quality Management District Manual of Procedures, Volume VI, Section 1, Ground Level Monitoring for Hydrogen Sulfide and Sulfur Dioxide (July 20, 1994) with the following amendments:
 - a. The wind direction shall be continuously measured and recorded to within 5 degrees of arc, and wind speed shall be continuously measured and recorded to within 0.25 miles per hour (mph) at wind speeds less than 25 mph and with a threshold no greater than 0.2 mph.
 - b. The meteorological instruments and siting requirements shall comply with the guidelines in "Quality Assurance Handbook for Air Pollution Measurements Systems, Volume IV, Meteorological Measurements Version 2.0," EPA-454/B-08-002, March 2008.
 - c. The gas standards shall be restandardized against the reference wet chemical method at a minimum of once every 12 months, or be standardized using National Institute of Standards and Technology (NIST) standard gases.

M:\TITLEV\Attachments updated\54B2 (08-10-18).docx

Ventura County Air Pollution Control District
Rule 55 Applicable Requirements
Fugitive Dust

Rule 55, "Fugitive Dust"
Adopted 06/10/08, District-Enforceable

This permit attachment will become federally enforceable when Rule 55 is approved by EPA as part of the SIP.

Applicability:

This attachment applies to any operation, disturbed surface area, or man-made condition at this stationary source that is capable of generating dust. These operations may include bulk material handling, earth-moving, construction, demolition, storage piles, unpaved roads, track-out, or off-field agricultural operations.

All definitions listed in Section H of Rule 55 are applicable to this attachment. The Rule 55 definition section includes the following definitions: "disturbed surface area", "bulk material", "earth moving activities", "construction/demolition activities", "storage piles", "paved road", "track-out", and "off-field agricultural operations". All exemptions listed in Section D of Rule 55 are applicable to this attachment.

Conditions:

1. Pursuant to Rule 55.B.1, the permittee shall not cause or allow the emissions of fugitive dust from any applicable source such that the dust remains visible beyond the midpoint (width) of a public street or road adjacent to the property line of the emission source or beyond 50 feet from the property line if there is not an adjacent public street or road.
2. Pursuant to Rule 55.B.2, the Permittee shall not cause or allow the emissions of fugitive dust from any applicable source such that the dust causes 20 percent opacity or greater during each observation and the total duration of such observations (not necessarily consecutive) is a cumulative 3 minutes or more in any one (1) hour. Only opacity readings from a single source shall be included in the cumulative total used to determine compliance. Compliance with the opacity limit shall be determined by using EPA Method 9 with the modifications listed in Section F of Rule 55.
3. Pursuant to Rule 55.B.3, the permittee shall not allow track-out to extend 25 feet or more in length unless at least one of the following three control measures is utilized: track-out area improvement, track-out prevention, or track-out removal. These control measures are detailed in Rule 55.B.3.a.

4. Pursuant to Rule 55.B.3.b, notwithstanding other track-out requirements, all track-out shall be removed at the conclusion of each workday or evening shift subject to the conditions listed in Section 55.B.3.b.
5. Pursuant to Rule 55.C, the permittee shall comply with the specific activity requirements detailed in Section C of Rule 55, for earth-moving, bulk material handling, and truck hauling activities, as applicable.
6. The permittee shall comply with the specific recordkeeping requirements listed in Section E of Rule 55, as applicable.
7. On an annual basis, the permittee shall certify that all applicable sources of dust at this stationary source are operating in compliance with Rule 55. The permittee may also certify annually that there are no operations, disturbed surface areas, or man-made conditions at this stationary source that are subject to Rule 55.

M:\TITLEV\Attachments updated\55.docx

Ventura County Air Pollution Control District
Rule 57.1 Applicable Requirements
Particulate Matter Emissions from Fuel Burning Equipment

Rule 57.1, "Particulate Matter Emissions from Fuel Burning Equipment"
Adopted 01/11/05, Federally Enforceable

Applicability:

This attachment applies to fuel burning equipment such as boilers, steam generators, process heaters, water heaters, space heaters, flares, and gas turbines. This attachment does not apply to internal combustion engines, jet engine test stands and rocket engine test stands, and rocket propellant testing devices and rocket fuel testing devices. This attachment also does not apply to exhaust gas streams containing particulate matter that was not generated by the combustion of fuel; such exhaust gas streams are subject to Rule 52 and Rule 53.

Conditions:

1. Pursuant to Section B of Rule 57.1, emissions of particulate matter shall not exceed 0.12 pounds per million BTU of fuel input.

Particulate matter is defined as any material, except uncombined water, that exists in a finely divided form as a liquid or solid at standard conditions. Standard conditions are: a gas temperature of 68 degrees Fahrenheit (20 degrees Celsius) and a gas pressure of 14.7 pounds per square inch (760 mm. Hg) absolute.

2. Upon request of the District Compliance Division, compliance shall be determined by independent source test using CARB Method 5. The total particulate catch shall include the filter catch, probe catch, impinger catch, and the solvent extract, as specified in CARB Method 5. Any other appropriate test method may be used with prior written approval by the District, the California Air Resources Board, and the U.S. Environmental Protection Agency.
3. Periodic monitoring is not necessary to certify compliance with Rule 57.1. To certify compliance, a reference to the Rule 57.B District analysis dated December 3, 1997 is sufficient.

M:\TITLEV\Attachments updated\57.1 (01-11-05).docx

Ventura County Air Pollution Control District
Rule 64 Applicable Requirements
Sulfur Content of Fuels - Gaseous Fuel Requirements

Rule 64, "Sulfur Content of Fuels"
Adopted 04/13/99, Federally Enforceable

Applicability:

This attachment applies to all combustion emissions units at this stationary source while the emissions units are combusting gaseous fuels. Rule 64 shall not apply to any flare gas combustion, where no useful energy is produced, and which is subject to Rule 54, "Sulfur Compounds."

Conditions:

1. Pursuant to Rule 64, no person shall burn at any time gaseous fuel containing sulfur compounds in excess of 50 grains per 100 cubic feet of gaseous fuel (788 ppmv), calculated as hydrogen sulfide at standard conditions, unless specifically exempted by Rule 64.
2. If only Public Utilities Commission-regulated natural gas, propane, or butane is combusted at this facility, it will be assumed that the permittee is complying with Rule 64 without additional periodic monitoring requirements. Any person claiming this exemption shall maintain records sufficient to substantiate the use of these fuels.
3. If other than Public Utilities Commission-regulated natural gas, propane, or butane is being combusted, the permittee shall analyze the sulfur content of the fuel on an annual basis using South Coast AQMD Method 307-94 - Determination of Sulfur in a Gaseous Matrix or by ASTM D1072-90 (1994), Standard Test Method for Total Sulfur in Fuel Gases.

Alternatively, when measuring the sulfur content of landfill or oilfield gaseous fuel, permittee may use the colorimetric method ASTM D 4810-88 (Reapproved 1994) or the ASTM D4084-94 (Lead Acetate Reaction Rate Method) and may assume that the hydrogen sulfide content of the fuel gas adequately represents the total sulfur content. However, if the sulfur content as measured by ASTM D4810-88 or ASTM D4084-94 equals or exceeds 200 ppmv, then only South Coast AQMD Method 307-94 or ASTM D1072-90 (1994) shall be used to determine compliance.

The applicable ranges of some ASTM methods mentioned above are not adequate to measure the levels of sulfur in some fuel gases. Dilution of samples before analysis may be used subject to the verification of the dilution ratio.

Permittee may use the colorimetric method ASTM D 4810-88 (Reapproved 1994) for the measurement of the sulfur content of gaseous fuels other than landfill or oilfield gas only if written approval has been granted by the District and by US EPA.

4. Monitoring of the sulfur content of landfill or oilfield gaseous fuel by the permittee shall be at least quarterly if any of the following conditions apply:
 - a. Any sulfur measurement exceeds 394 ppmv, calculated as hydrogen sulfide at standard conditions.
 - b. A stationary source is new.
 - c. The permittee has not reported historical measurements of hydrogen sulfide of the landfill or oilfield gaseous fuel performed within the previous three years in writing to the District for a stationary source.

An operator may have the sulfur content of landfill or oilfield gaseous fuel monitored annually only, instead of quarterly, by satisfying the following provisions:

- a. During four consecutive calendar quarters, each sulfur content measurement shall not exceed 394 ppmv, calculated as hydrogen sulfide at standard conditions, and
- b. Submit a written request to the District for a reduction in monitoring frequency. This request shall contain backup documentation including monitoring reports that document the above provision. Requests for a reduction in monitoring frequency are not effective until written approval by the District is received by the operator.

This annual fuel analysis, and the quarterly analyses if applicable, shall be maintained at the facility and a copy of the annual analysis shall be provided to the District with the annual compliance certification.

**Ventura County Air Pollution Control District
Rule 64 Applicable Requirements
Sulfur Content of Fuels - Liquid Fuel Requirements**

**Rule 64, "Sulfur Content of Fuels"
Adopted 04/13/99, Federally Enforceable**

Applicability:

This attachment applies to all combustion emissions units at this stationary source while the emissions units are combusting liquid fuels. This attachment does not apply to any combustion emission unit with sulfur emission controls.

Conditions:

1. Pursuant to Rule 64, no person shall burn any liquid fuels with a sulfur content in excess of 0.5 percent, by weight, unless specifically exempted by Rule 64.
2. If only ARB-quality reformulated gasoline or ARB-certified diesel fuel is combusted at this facility, it will be assumed that the permittee is complying with Rule 64 without additional periodic monitoring requirements. Any person claiming this exemption shall maintain records sufficient to substantiate the use of these fuels.
3. If other than ARB-quality reformulated gasoline or ARB-certified diesel fuel is being combusted, for each liquid fuel delivery permittee shall either obtain the fuel supplier's certification, or shall test the sulfur content of the fuel using ASTM Method D4294-98 or D2622-98, to ensure that compliance with Rule 64 is being maintained. For liquid fuels, operators of electric power generation units may use the sampling and analysis methods prescribed in Code of Federal Regulations 40CFR Part 75 Appendix D.2.2. The fuel supplier's certification may be provided once for each purchase lot, if records are kept of the purchase lot number of each delivery.

The fuel sulfur content by weight data shall be maintained at the facility and shall be provided with the annual compliance certification.

M:\TITLEV\Attachments updated\64B2(4-13-99).docx

**Ventura County Air Pollution Control District
Rule 71.1.C Applicable Requirements
Crude Oil Production and Separation - Produced Gas**

**Rule 71.1, "Crude Oil Production and Separation"
Adopted 06/16/92, Federally-Enforceable**

**Rule 74.10, "Components at Crude Oil and Natural Gas Production and Processing
Facilities"
Adopted 03/10/98, Federally-Enforceable**

Applicability:

This attachment applies to the emissions of produced gas from equipment used in the production, gathering, storage, processing, and separation of crude oil and natural gas from any petroleum production unit prior to custody transfer. Specifically, this attachment applies to gas collection systems that are hard-piped and closed systems that direct all produced gas to a fuel or sales gas system or to a flare.

Conditions:

1. Pursuant to Rule 71.1.C.1, the emissions of produced gas shall be controlled at all times using a properly maintained and operated closed system that directs all gas, except gas used in a tank battery vapor recovery system, to one of the following:
 - a. A fuel or sales gas system
 - b. A flare that combusts reactive organic compounds
2. Pursuant to Rule 71.1.C.2, the provisions of Rule 71.1.C.1 shall not apply to wells which are undergoing routine maintenance, or to exploratory wells (during the first two weeks of production) if the composition of the produced gas is unknown (i.e., new reservoir) and there are no existing gas handling systems within 150 feet of the well.
3. Permittee shall annually certify the produced gas collection system to ensure that compliance with Rules 71.1.C.1 is being maintained. This annual certification shall include a visual inspection assuring that the produced gas collection system is a closed system.
4. If a flare is used to control the produced gas, permittee shall inspect the flare on a quarterly basis to ensure that it is operating properly. A record of these inspections shall be maintained at the facility and shall be submitted to the District upon request.

5. The gas collection system's gas and liquid piping connections are components subject to the leak requirements of Rule 74.10, "Components at Crude Oil and Natural Gas Production and Processing Facilities". Compliance with Rule 74.10 at the gas collection system ensures compliance with the maintenance requirements of Rule 71.1.C.1.

M:\TITLEV\Attachments updated\711C.docx

Ventura County Air Pollution Control District
Rule 71.4.B.1 Applicable Requirements
First Stage Sump Prohibition

Rule 71.4, "Petroleum Sumps, Pits, Ponds, and Well Cellars"
Adopted 06/08/93, Federally-Enforceable

Applicability:

This attachment applies to any first stage production sump at this stationary source. A first stage production sump is a sump that receives a stream of petroleum material directly from wells or a field gathering system. A sump is a receptacle, formed primarily of earthen materials, although it may be lined with artificial materials. A sump is further defined as "in continuous use for separating oil, water, sand, or other material in petroleum production operations".

Conditions:

1. Pursuant to Rule 71.4.B.1, no person shall install, maintain, or operate a first stage production sump. A first stage production sump is a sump that receives a stream of petroleum material directly from wells or a field gathering system.
2. In order to ensure that compliance with Rule 71.4.B.1 is being maintained, permittee shall annually certify that there are no first stage production sumps at the facility.

M:\TITLEVA\Attachments updated\714B1.docx

**Ventura County Air Pollution Control District
Rule 71.4.B.3 Applicable Requirements
Well Cellar Storage Prohibition**

**Rule 71.4, "Petroleum Sumps, Pits, Ponds and Well Cellars"
Adopted 06/08/93, Federally Enforceable**

Applicability:

This attachment applies to any well cellar at this stationary source. This attachment addresses the requirements of Rule 71.4.B.3 which prohibits the storage of crude oil or petroleum material in a well cellar. Rule 71.4 applies to well cellars at facilities where crude oil or petroleum material is produced, gathered, separated, processed, or stored.

A well cellar is a lined or unlined area around one or more oil wells, allowing access to the wellhead components for servicing and/or installation of blowout prevention equipment.

Conditions:

1. Pursuant to Rule 71.4.B.3, no person shall store crude oil or petroleum material in a well cellar except during periods of equipment maintenance or well workover. In no case shall storage occur for more than five (5) calendar days.
2. Pursuant to Rule 71.4.C, the provisions of Rule 71.4 shall not apply to well cellars used in an emergency, if clean-up procedures are implemented within 24 hours after each emergency occurrence and if clean-up procedures are completed within fifteen (15) calendar days.
3. Pursuant to Rule 71.4.D.2, any person storing crude oil in a well cellar during periods of equipment maintenance or well workover shall maintain records, which may include but are not limited to, workover invoice documents, indicating the date(s) the material was stored in the well cellar or the date(s) of workover activity. These records shall be submitted to the District upon request.
4. Pursuant to Rule 71.4.D.3, any person claiming exemption to this rule pursuant to emergency use (Condition No. 2 above), shall maintain records to justify the exemption.

Ventura County Air Pollution Control District
Rule 74.6 Applicable Requirements
Surface Cleaning and Degreasing

Rule 74.6, "Surface Cleaning and Degreasing"

Adopted 11/11/03, Federally Enforceable

Applicability:

This attachment applies to all solvent cleaning activities at this stationary source, except those activities listed in Condition No. 11 that are exempt pursuant to Section E of Rule 74.6. This attachment does not apply to substrate surface preparation regulated by other APCD surface coating, adhesive, ink, resin, and solvent rules. "Solvent" is defined as any ROC-containing liquid used to perform solvent cleaning. "Solvent cleaning" is defined as the use of organic solvent to remove loosely held uncured adhesives, uncured inks, uncured coatings, uncured resins, and other contaminants which include, but are not limited to, dirt, soil, lubricants, coolant, moisture, grease, and fingerprints, from parts, tools, machinery, equipment, and general work areas.

This attachment also contains requirements, pursuant to Rule 74.6, for cold cleaners. A cold cleaner is defined in Rule 74.6 as any batch operated equipment designed to contain liquid solvent that is operated below the solvent's boiling point to carry out solvent cleaning operations. A specific type of cold cleaner is a "remote reservoir cold cleaner" which is a device in which solvent is moved through a sink-like work area for cleaning parts and drains immediately, without forming a pool, through a single drain hole less than 100 square centimeters (15.5 square inches) in area into an enclosed container that is not accessible for soaking parts. The freeboard height for remote reservoir cold cleaners is the distance from the top of the solvent drain to the top of the tank.

This attachment does not apply to solvent cleaning where an emission control system is used pursuant to Rule 74.6.B.5 or where an alternative cleaning system is used pursuant to Rule 74.6.B.6. Pursuant to APCD Rule 23.F.7, solvents used by the permittee for facility, ground, and building maintenance and repair are exempt from the requirement to have a permit. However, unless exempted by Rule 74.6.E, such solvents are required to comply with Rule 74.6.

Conditions:

1. Pursuant to Rule 74.6.B.1, no person shall perform solvent cleaning using solvent that exceeds the following limits:
 - a. Solvents used for application equipment cleanup, and all other cleanup of uncured coatings, adhesives, inks, or resins, shall not exceed an ROC content of 900 grams per liter and an ROC composite partial pressure of 33 mmHg at 20°C, as applied.

- b. Solvents used for cleaning of electronic components, electrical apparatus components, medical devices, or aerospace components shall not exceed an ROC content of 900 grams per liter and an ROC composite partial pressure of 33 mmHg at 20°C, as applied.
 - c. Solvents used for cleaning for purposes other than those listed in (a) and (b) above shall not exceed an ROC content of 25 grams per liter, as applied.
2. Pursuant to Rule 74.6.B.2, no person shall perform solvent cleaning using a solvent with an ROC content greater than 25 grams per liter unless one of the following cleaning devices or methods is used:
 - a. Wipe cleaning where solvent is dispensed to wipe cleaning materials from containers that are kept closed to prevent evaporation, except while dispensing solvent or replenishing the solvent supply;
 - b. Non-atomized solvent flow, dip, or flush method where pooling on surfaces being cleaned is prevented or drained, and all solvent runoff is collected in a manner that enables solvent recovery or disposal. The collection system shall be kept closed to prevent evaporation except while collecting solvent runoff or emptying the collection system;

If the cleaning method has a solvent capacity more than one gallon, a cold cleaner or remote reservoir cold cleaner meeting the equipment and operating requirements of Condition Nos. 8, 9, and 10 of this attachment (Sections C and D of Rule 74.6) shall be used to comply with this requirement.
 - c. Application of solvent from a hand held spray bottle, squirt bottle or other closed container with a capacity of one liter or less;
 - d. A properly used enclosed gun washer or low emission spray gun cleaner.
3. Pursuant to Rule 74.6.B.3.a, no person shall allow liquid cleaning solvent to leak from any equipment or container.
4. Pursuant to Rule 74.6.B.3.b, no person shall specify, solicit, supply, or require any cleaning solvent or solvent cleaning equipment intended for uses governed by Rule 74.6 if such use would violate Rule 74.6. This prohibition applies to all written and oral contracts under which solvent cleaning operations subject to Rule 74.6 are to be conducted at any location in Ventura County.
5. Pursuant to Rule 74.6.B.3.c, no person shall use more than one gallon per week of

solvents containing methylene chloride, perchloroethylene, trichloroethylene, 1,1,1-trichloroethane, carbon tetrachloride, or chloroform, or any combination of these solvents, in a total concentration greater than 5 percent by weight, for cold cleaning except in a cold cleaner operated in accordance with National Emission Standards for Halogenated Solvent Cleaning, 40 CFR Parts 9 and 63, Subpart T, Sections 63.460 through 63.469 (Degreasing MACT Standards). Any person that uses the above solvent in quantities less than one gallon per week shall maintain records of the volume and formulation of such solvent on an as-used basis (recording use each day such material is used). Records shall be saved for at least five (5) years from the date of each record and shall be made available to District personnel upon request.

6. Pursuant to Rule 74.6.B.4.a, all ROC-containing solvents shall be stored in non-absorbent, non-leaking containers that shall be kept closed at all times except when filling or emptying.
7. Pursuant to Rule 74.6.B.4.b, waste solvent and waste solvent residues shall be disposed of in a manner conforming with Division 20, Chapter 6.5 of the California Health and Safety Code.
8. Pursuant to Rule 74.6.C.1, all cold cleaners, except remote reservoir cold cleaners, shall be equipped with the following devices:
 - a. A drying rack suspended above the solvent, or other facility for draining cleaned parts such that the drained solvent is returned to the cleaner.
 - b. A cover that prevents the solvent from evaporating when not processing work in the cleaner. If high volatility solvent is used, the cover must be a sliding, rolling, or guillotine (bi-parting) type that is designed to easily open and close, or it must be designed to be easily operated with one hand. A high volatility solvent is an unheated solvent with an ROC composite partial pressure of greater than 2 mmHg @ 20°C.
 - c. A freeboard height of at least 6 inches (15.2 centimeters), if low volatility solvent is used. A low volatility solvent is an unheated solvent with an ROC composite partial pressure of 2 mmHg or less @ 20°C.
 - d. At least one of the following control devices, if high volatility solvent is used:
 1. A freeboard height such that the freeboard ratio is at least 0.75.
 2. A water cover if the solvent is insoluble in and heavier than water.
 - e. A permanent conspicuous mark locating the maximum allowable solvent level that conforms with the applicable freeboard height requirement in Condition No. 8.c or 8.d.1.

- f. A permanent conspicuous label or sign summarizing the applicable operating requirements appropriate for cold cleaning operations.
9. Pursuant to Rule 74.6.C.2, remote reservoir cold cleaners shall be equipped with the following devices:
 - a. A permanent conspicuous label or sign summarizing the applicable operating requirements appropriate for cold cleaning operations.
 - b. A sink-like work area that is sloped sufficiently towards the drain to preclude pooling of solvent.
 - c. A single drain hole, less than 100 square centimeters (15.5 square inches) in area, for the solvent to flow from the sink into the enclosed reservoir.
 - d. A freeboard height of at least 6 inches (15.2 centimeters).
 - e. A cover for the drain when no work is being processed in the cleaner and high volatility solvent is used. If low volatility solvent is used, a cover is not required.
10. Pursuant to Rule 74.6.D, any person who operates a cold cleaner shall conform to the following operating requirements:
 - a. The operator shall drain cleaned parts of all solvent until dripping ceases to ensure that the drained solvent is returned to the cleaner.
 - b. Solvent agitation, where necessary, shall be achieved using pump recirculation, a mixer, or ultrasonics. Air agitation shall not be used.
 - c. If a solvent flow is utilized, only a solid fluid stream (not a fine, atomized, or shower type spray) shall be used.
 - d. The pressure of the solvent flow system shall be such that liquid solvent does not splash outside the container.
 - e. No person shall remove or open any required device designed to cover the solvent unless work is being processed in the cleaner or maintenance is being performed on the cleaner.
 - f. The cleaning equipment and emission control equipment shall be operated and maintained in proper working order.
 - g. The cleaning of porous or absorbent materials such as cloth, leather, wood, or rope is prohibited. This provision shall not apply to paper gaskets or paper filters.
11. Pursuant to Rule 74.6.E.1, Rule 74.6 (all requirements of this permit attachment) shall not

apply to:

- a. Cleaning activities using Clean Air Solvent, or a solvent with an ROC-content no more than 25 grams per liter as applied. A "Clean Air Solvent" is a solvent certified by the South Coast Air Quality Management District as a Clean Air Solvent.
 - b. The use of up to 160 fluid ounces of non-refillable aerosol cleaning products per day, per facility.
 - c. Janitorial cleaning including graffiti removal.
 - d. Cleaning carried out in vapor degreasers or motion picture film cleaning equipment.
 - e. Any cleaning device or mechanism regulated by National Emission Standards for Halogenated Solvent Cleaning, 40 CFR Parts 9 and 63, Subpart T, Sections 63.460 through 63.469 (Degreasing MACT Standards).
 - f. Cleaning operations subject to any of the following rules:
 - Rule 74.3, Paper, Fabric and Film Coating Operations
 - Rule 74.5.1, Petroleum Solvent Dry Cleaning
 - Rule 74.5.2, Synthetic Solvent Dry Cleaning
 - Rule 74.19, Graphic Arts Operations
 - Rule 74.19.1, Screen Printing Operations
 - Rule 74.21, Semiconductor Manufacturing
 - g. Stripping of cured coating (e.g.; stripping), cured adhesive (e.g.; debonding, ungluing), cured ink, or cured resin.
 - h. The use of solvent for purposes other than solvent cleaning activities.
12. Pursuant to Rule 74.6.E.2, Rule 74.6.B.1 (Condition No. 1 of this attachment) shall not apply to:
- a. Cleaning operations required to comply with any ROC content and/or composite vapor pressure limit in any of the following rules:
 - Rule 74.12, Surface Coating of Metal Parts and Products
 - Rule 74.13, Aerospace Assembly and Component Manufacturing Operations
 - Rule 74.14, Polyester Resin Material Operations
 - Rule 74.18, Motor Vehicle and Mobile Equipment Coating Operations
 - Rule 74.20, Adhesives and Sealants
 - Rule 74.24, Marine Coating Operations

Rule 74.24.1, Pleasure Craft Coating Operations
Rule 74.30, Wood Products Coatings

- b. Cleaning of ultraviolet lamps used to cure ultraviolet inks coatings, adhesives or resins.
- c. Cleaning of solar cells, laser hardware, scientific instruments, or high-precision optics.
- d. Cleaning conducted in laboratory tests and analyses including quality assurance/quality control applications, or bench scale or short-term (less than 2 years) research and development programs.
- e. Removal of elemental sodium from the inside of pipes and lines.
- f. Cleaning of mold release compounds from molds.
- g. Cleaning of tools used to cut or abrade cured magnetic oxide coatings.
- h. Cleaning of aerospace assembly and subassembly surfaces that are exposed to strong oxidizers or reducers such as nitrogen tetroxide, liquid oxygen or hydrazine.
- i. Cleaning of paper gaskets.
- j. Cleaning of clutch assemblies where rubber is bonded to metal by means of an adhesive.
- k. Cleaning of hydraulic actuating fluid from filters and filter housings.
- l. Removal of explosive materials and constituents from equipment associated with manufacturing, testing or developing explosives.
- m. Manufacturing cleaning of nuts and bolts designed for automotive racing applications, in a cold cleaner complying with Sections C and D of Rule 74.6 using solvent with an ROC content no more than 900 grams per liter and a ROC composite partial pressure no more than 5 mm Hg @ 20C.
- n. Cleaning of precision-lapped mechanical seals in pumps that handle liquefied gasses, in a cold cleaner complying with Sections C and D of Rule 74.6 using solvent with an ROC content no more than 900 grams per liter and a ROC composite partial pressure no more than 5 mm Hg @ 20C.
- o. Facility wide use of less than 1 gallon per week of non-compliant solvent where compliant solvents are not available. Any person claiming this exemption shall

maintain records of the volume and formulation of non-compliant solvent used on an as-used basis (recording use each day such material is used). Records shall be saved for at least five (5) years from the date of each record and shall be made available to District personnel upon request.

13. Pursuant to Rule 74.6.E.3, Rule 74.6 Sections B.1 and B.2 (Condition Nos. 1 and 2 of this attachment) shall not apply to aircraft engine gas path cleaning or stationary gas turbine gas path cleaning using solvent with an ROC content of 200 g/l or less, as applied.
14. Pursuant to Rule 74.6.F, the permittee shall maintain a current material list showing each ROC containing material used in solvent cleaning activities. The list shall summarize the following information:
 - a. Solvent name and manufacturer's description.
 - b. All intended uses of the solvent at the facility, classified as follows:
 1. Cleanup, including application equipment cleaning, or
 2. Cleaning of electronic components, electrical apparatus components, medical devices, or aerospace components, or
 3. Solvent used pursuant to an exemption in Rule 74.6.E (specify the exemption claimed).
 - c. The ROC content in units of grams per liter of material (and ROC composite partial pressure in units of mm Hg @ 20C, if applicable) of the solvent.
 - d. If the solvent is a mix of materials blended by the operator, a record of the mix ratio.

This information shall be made available to District personnel upon request.

15. Permittee shall maintain the above records and conduct periodic facility inspections, and an annual compliance certification to ensure that compliance with Rule 74.6 is being maintained. Upon request of the District, compliance with Rule 74.6 shall be determined using the following methods:
 - a. Pursuant to Rule 74.6.G.1, the ROC content of materials shall be determined by EPA Test Method 24 (40 CFR Part 60, Appendix A).
 - b. Pursuant to Rule 74.6.G.4, the identity of components in solvents shall be determined using manufacturer's formulation data or by using ASTM E168-67, ASTM E169-87, or ASTM E260-85.

- c. Pursuant to Rule 74.6.G.5, ROC composite partial pressure of a solvent shall be calculated using a widely accepted published source such as: Boublik, T., V. Fried and E. Hala, "The Vapor Pressure of Pure Substances," Elsevier Scientific Publishing Co., New York (1973), Perry's Chemical Engineers Handbook, McGraw-Hill Book Company, CRC Handbook of Chemistry and Physics, Chemical Rubber Publishing Company (1986-1987), and Lange's Handbook of Chemistry, John A. Dean, editor, McGraw-Hill Book Company (1985). The true vapor pressure of a component in a solvent mix may be determined by ASTM Method D2879-86. The ROC composite partial pressure of a solvent mix consisting entirely of ROC may be determined by ASTM Method D2879-86.
- d. Pursuant to Rule 74.6.G.6, the active and passive solvent losses from spray gun cleaning systems shall be determined using South Coast Air Quality Management District's "General Test Method for Determining Solvent Losses from Spray Gun Cleaning Systems" dated October 3, 1989. The test solvent for this determination shall be any lacquer thinner with a minimum vapor pressure of 105 mm Hg at 20°C. The minimum test temperature shall be 15°C.
- e. Pursuant to Rule 74.6.G.7, initial boiling point of solvent shall be determined by ASTM 1078-78 or by using a published source such as listed in Rule 74.6.G.5.

M:\TITLEV\Attachments updated\746 (03-15-19).docx

Ventura County Air Pollution Control District
Rule 74.10 Applicable Requirements
Components at Crude Oil and Natural Gas Production and Processing Facilities

Rule 74.10, "Components at Crude Oil and Natural Gas Production and Processing Facilities"

Adopted 03/10/98, Federally Enforceable

Applicability:

This attachment applies to the crude oil and gas production facilities, pipeline transfer stations, and to natural gas processing facilities, at this stationary source. This attachment summarizes the fugitive leak and leak inspection requirements of Rule 74.10.

A crude oil and gas production facility is defined as an onshore or offshore facility at which crude petroleum and natural gas production and handling are conducted, as defined in the SIC Code as Industry No. 1311, Crude Petroleum and Natural Gas. A pipeline transfer station is defined as a facility that handles the transfer or storage of crude oil in pipelines. A natural gas processing facility is defined as a facility engaged in the separation of natural gas liquids from field gas and/or fractionation of the liquids into natural gas products, such as ethane, propane, butane, and natural gasoline. Excluded from the definition are compressor stations, dehydration units, sweetening units, field treatment, underground storage facilities, liquefied natural gas units, and field gas gathering systems unless these facilities are located at a natural gas processing plant. This attachment does not apply to petroleum refineries.

Conditions:

1. Pursuant to Rule 74.10.B, the operator shall identify all leaking components that cannot be immediately repaired. This identification shall consist of readily visible labels, tags, or other such system approved by the APCO, in writing, that enables the District and the operator to locate and identify each leaking component. Identification tags and labels shall remain visible for at least one year from the date attached.

As detailed in Rule 74.10.K.14, a leak is defined as any major gas leak, minor gas leak, major liquid leak or minor liquid leak. A leak is not a gaseous emission from a pneumatic control valve if it occurs when the valve is in the act of opening or closing. As detailed in Rule 74.10.K.3, a component is defined as any valve, stuffing box, dump lever arm, open ended line, fitting, pump seal, compressor seal, pressure relief valve, diaphragm, hatch, sight glass or meter. As detailed in Rule 74.10.K.16, a leak repair is any corrective action taken for the purposes of reducing a component leak to the lowest achievable level or at least below 1,000 ppmv for gas leaks and three drops per minute for liquid leaks using the best modern practices.

2. Pursuant to Rule 74.10.C.1, hatches shall be closed at all times except during sampling, adding of process material through the hatch, or attended maintenance operations.
3. Pursuant to Rule 74.10.C.2, no person shall use a component that emits a major gas leak, major liquid leak or minor liquid leak and the applicable maximum leak threshold for that component category, as listed in Attachment 1 of Rule 74.10, has been exceeded at the facility in any calendar quarter. The provisions of Rule 74.10.C.2 shall not apply to components that are tagged and repaired in accordance with Rules 74.10.D and 74.10.F.

For the purpose of complying with the operating requirements in Rule 74.10.C.2, any fugitive emissions leak originating at a tank seam, broken pipe or any other nondesigned opening in a process unit shall be considered an "other component" leak for the purpose of Attachment 1 of Rule 74.10.

A major gas leak, major liquid leak, and minor liquid leak are defined in Subsections K.17, K.18, and K.20 of Rule 74.10, respectively.

4. Pursuant to Rule 74.10.D.1, at natural gas processing plants, operators shall inspect with or without instrumentation all accessible operating pump seals, compressor seals, and pressure relief valves in service for leaks or indications of leaks once during every operating shift or every eight-hour period, whichever is greater.
5. Pursuant to Rule 74.10.D.2, at oil and gas production facilities and pipeline transfer stations, operators shall inspect with or without instrumentation all operating pump seals, compressor seals, pressure relief valves in service, and polished rod stuffing boxes for leaks or indications of leaks as follows:
 - a. Inspection frequency at manned facilities shall be at least once per day except when operators do not report to work at a facility at any time during that day.
 - b. Inspection frequency at unmanned facilities shall be at least once per week.
6. Pursuant to Rule 74.10.D.3, any gaseous leaks or indications of gaseous leaks discovered by inspection, that cannot be immediately repaired, shall be measured using EPA Method 21. The operator shall perform this leak measurement as follows:
 - a. For leaks detected during normal business hours, the leak measurement shall be performed as soon as feasible but no later than 24 hours after detection. If this 24 hour deadline occurs on a weekend or holiday, then the deadline is shifted to the end of the next normal business day.
 - b. For leaks detected during holidays, weekends or after business hours, the leak measurement shall be performed as soon as feasible but no later than the end of

the next normal business day.

7. Pursuant to Rule 74.10.D.4, immediately after being placed into service, an operator shall inspect all new, replaced or repaired fittings, including flanges and threaded connections, for leaks using EPA Method 21.
8. Pursuant to Rule 74.10.D.5, operators shall inspect all components, except for the following, at least every calendar quarter for gaseous leaks using EPA Method 21.
 - a. Inaccessible components or unsafe to monitor components shall be inspected for leaks by the operator at least annually using EPA Method 21.
 - b. Threaded connections and flanges shall be inspected for leaks by the operator using EPA Method 21 annually, unless the operator has designated them in the Operator Management Plan as exempt from all inspection requirements and subject to a zero leak threshold.
9. Pursuant to Rule 74.10.D.6, a pressure relief valve shall be inspected using EPA Method 21 within 3 calendar days after every known pressure release.
10. Pursuant to Rule 74.10.D.7, upon detection, operators shall affix a visible, weatherproof tag to all leaking components awaiting repair. The tag shall remain affixed until the component is repaired free of leaks as shown by re-inspection.

If the leak is gaseous, the operator shall include the following on the tag: date and time of leak detection, date and time of leak measurement; and the concentration (ppmv) measured using EPA Method 21.

If the leak is liquid, the operator shall include the following on the tag: date and time of leak detection; and whether leak is minor or major.

A tag may also be some other system approved in writing by the APCO that demonstrates to District personnel that the operator has detected a component leak awaiting repair and contains all of the information required to be on tags by Rule 74.10.D.7.

11. Pursuant to Rule 74.10.D.8, notwithstanding the requirements of Rule 74.10.D.5, operators may inspect components annually instead of quarterly at a facility by satisfying all the following provisions, except that compressor seals, pressure relief valves, polished rod stuffing boxes, and pump seals shall not be eligible for this reduction in inspection frequency:
 - a. During 4 consecutive calendar quarters, successfully operate and maintain all components at the facility so that no more than 0.5 percent of the total

components inspected, excluding polished rod stuffing boxes, have liquid leaks or major gas leaks that have not been immediately repaired.

- b. A Notice of Violation from the District for a violation of Rule 74.10.C.2 was not received by the operator for the facility during the previous twelve months.
 - c. Submit a written request to the District for a reduction in inspection frequency. This request shall contain backup documentation including inspection reports that demonstrates that the above performance level in Rule 74.10.D.8.a has been achieved. Requests for a reduction in inspection frequency are not effective until written approval by the APCO is received by the operator.
12. Pursuant to Rule 74.10.D.9, an annual inspection frequency approved in Rule 74.10.D.8 shall revert to the inspection frequency specified in Rule 74.10.D.5 should the sum of liquid leaks and major gas leaks, not including leaks from polished rod stuffing boxes, exceed 0.5 percent of the total components inspected per inspection period or should the operator receive a Notice of Violation from the District for violation of Rule 74.10.C.2 for that facility.
13. Pursuant to Rule 74.10.E.1, each operator shall submit an Operator Management Plan to the APCO for approval. If the APCO fails to respond to the Plan in writing within 90 days after it has been received, then it shall be deemed approved. No provision in the Plan, approved or not, shall conflict with or take precedence over any provision of this rule. The Plan shall identify any component exempt from this rule or part of this rule, and describe the procedures which the operator intends to use to comply with the requirements of this rule. The Plan shall include:
- a. Establishment of a data base of every leaking component that cannot be immediately repaired. The following parameters shall be included:
 - 1) Identification number, name or code.
 - 2) Component type, process unit and location.
 - 3) Dates found leaking and repair description for each leak found.

This identification provision is for inspection, repair, replacement and recordkeeping purposes.

- b. Identification of critical process units.
- c. Identification of components for which exemption from Rule 74.10 is being claimed under Rule 74.10.G.1. Gaseous streams and liquid streams, exempted by

Rule 74.10, Subsections G.1.a, G.1.b, G.1.c, or G.1.e shall be verified by analysis of the ROC concentrations, and the results of such analyses shall be included.

- d. Identification of liquid streams or components for which exemption is being claimed from the operator inspection requirements under Rule 74.10.G.3. The results of any testing used to qualify a stream for exemption shall be included.
 - e. Whether flanges or threaded fittings are exempt from all inspection requirements and subject to a zero leak threshold or whether flanges or threaded fittings are subject to annual inspection requirements and a one percent leak threshold as specified in Attachment 1 of Rule 74.10.
 - f. The inspection schedule to be followed.
 - g. Identification and description of any known hazard which may affect the safety of APCD personnel.
 - h. Identification of unmanned production facilities, if applicable.
14. Pursuant to Rule 74.10.E.2, the operator shall be required, upon written request by the APCO, to re-qualify, by analysis, the exemption(s) from the rule or part of the rule (Rule 74.10.G.1 and 74.10.G.3) if the exemption(s) may no longer be valid based on the changed composition of the process stream. The results of that analysis and any modification to the Plan shall be submitted to the District within 90 calendar days after receipt of the District request.
15. Pursuant to Rule 74.10.E.3, if the exempt status of a component is affected by a revision to Rule 74.10, then the Plan shall be modified accordingly by June 10, 1998.
16. Pursuant to Rule 74.10.E.4, existing operator management plans shall be updated no later than September 10, 1998, to include any provision that is needed to show compliance with Rule 74.10.
17. Pursuant to Rule 74.10.E.5, beginning September 10, 1998, each operator shall submit to the APCO, for approval in writing, an annual report to update the Operator Management Plan by no later than January 30 of each year. This report shall include any changes to exemptions, inspection schedule, or any other changes to the inspection and maintenance program. If no changes to the Plan have occurred over the past 12 months, then the operator shall indicate this in the annual report.

If the APCO fails to respond to the Plan update in writing within 90 days after it has been received, then it shall be deemed approved. No provision in the Plan, approved or not, shall conflict with or take precedence over any provision of Rule 74.10.

18. Pursuant to Rule 74.10.F.1, the operator shall minimize all component leaks immediately if feasible but no later than 1 hour following detection during normal business hours. Component leaks detected during holidays, weekends and after business hours shall be immediately minimized if feasible but not later than the next normal business day.
19. Pursuant to Rule 74.10.F.2, any noncritical component found leaking shall be replaced or repaired to a leak free condition, within the time periods in Table 1 of Rule 74.10. For gaseous leaks, the repair period shall start at the time of leak measurement. For liquid leaks, the repair period shall start at the time of leak detection. If the Table 1 deadline for repairing any major gas leak or any liquid leak falls on a Saturday, Sunday or holiday, then the deadline shall be shifted to the next normal business day.
20. Pursuant to Rule 74.10.F.3, the operator shall re-inspect repaired or replaced components for leaks as soon as practicable using EPA Method 21, but not later than one calendar month after the date on which the component is repaired.
21. Pursuant to Rule 74.10.F.4, any component leak identified by District personnel shall be repaired and inspected as required by Rule 74.10.F.
22. Pursuant to Rule 74.10.F.5, any open-ended line found to be leaking shall be sealed with a blind flange, cap, plug, or a second closed valve at all times except during operations requiring process fluid flow through the open-ended line or valve. If a second closed valve is used, the process side valve shall be closed first, after the completion of any operations requiring flow through the open-ended valve.
23. Pursuant to Rule 74.10.F.6, for major gas leaks (>50,000 ppm) or major liquid leaks from any critical compressor seal, pump seal, pressure relief valve or valve that cannot be repaired within the repair periods set forth in Table 1 of Rule 74.10, the operator shall replace or retrofit the leaking component with Best Available Control Technology (BACT) equipment, as approved by the APCO in writing, within one year from the date of leak detection, or during the next critical process unit shutdown, whichever occurs first.

For gas leaks less than or equal to 50,000 ppm or minor liquid leaks from critical components, or for leaks from critical components other than compressor seals, pump seals, pressure relief valves or valves, the owner or operator shall successfully repair or replace all leaking components within one year from leak detection or during the next critical process unit shutdown, whichever occurs first.

The operator shall notify the District in writing within 3 months after detecting a major gas leak (> 50,000 ppm) or major liquid leak from a critical compressor seal, pump seal, pressure relief valve, or valve if such leak cannot be repaired within the repair periods set

forth in Table 1 of Rule 74.10.

24. Pursuant to Rule 74.10.F.7, for a compressor seal, pump seal, pressure relief valve or valve that emits a total of 5 major leaks within a continuous 12 month period, the operator shall replace or retrofit the leaking component with BACT equipment, as approved by the APCO in writing, within one year from date of leak detection. The operator shall notify the District in writing within 3 months after a compressor, pump, pressure relief valve, or valve has had 5 major leaks in the previous 12 months.
25. Pursuant to Rule 74.10.G.1, the requirements of Rule 74.10 shall not apply to the following components that are verified in the Operator Management Plan:
 - a. Components, not at natural gas processing plants, with gaseous streams with ROC concentrations of 10 percent, by weight or less.
 - b. Components at natural gas processing plants with gaseous streams with ROC concentrations of one percent, by weight or less.
 - c. Components, not at natural gas processing plants, in liquid service, with ROC concentrations of 10 percent, by weight or less.
 - d. Underground components.
 - e. Components exclusively handling fluids if the fluid weight evaporated is 10 percent or less at 150 degrees Celsius.
26. Pursuant to Rule 74.10.G.2, the operator inspection requirements of Rule 74.10.D shall not apply to the following components. All other requirements of this rule shall still apply.
 - a. Pump seals, compressor seals, and pressure relief valves that are equipped with a closed-vent system to a vapor recovery system. The vapor disposal portion of the vapor recovery system shall consist of one of the following:
 - 1) A system which directs all vapors to a fuel gas system, a sales gas system, or a flare that combusts ROC.
 - 2) Any other system that processes all vapors and has a ROC vapor destruction or removal efficiency of at least 90 percent, by weight.
 - b. One-half inch and smaller stainless steel tube fittings that have been determined to be leak-free.

- c. Components in vacuum service.
 - d. Flanges or threaded connections that are designated in the Operator Management Plan as subject to the zero leak threshold specified in Attachment 1 of Rule 74.10.
27. Pursuant to Rule 74.10.G.3, the operator inspection requirements of Rule 74.10, Subsections D.1, D.2, D.4 and D.5 shall not apply to components that are inspected with or without instrumentation on a quarterly basis and are at oil and gas production facilities or pipeline transfer stations that handle liquids with the following properties and specified vapor recovery systems:
- a. Liquid having an API gravity of 20 degrees or less after the point of primary separation;
 - b. Liquid having an API gravity between 20 and 30 degrees which are located either:
 - 1) Downstream of a wellhead equipped with a casing vapor recovery system, provided that the vapor recovery system is operated at a pressure of less than 10 psig; or
 - 2) After the point of primary separation of oil and gas, provided the separation vessel is equipped with a vapor recovery system and is operated at a pressure of less than 25 psig.
28. Pursuant to Rule 74.10.G.4, an owner or operator may petition the APCO for exemption from the replacement or retrofit requirements in Rules 74.10.F.6 and 74.10.F.7 by submitting a cost evaluation for retrofitting or replacing a compressor, pump, pressure relief valve, or valve. Each petition shall include:
- a. A cost-effectiveness evaluation conducted in accordance with "BACT Cost-Effectiveness Procedures and Screening Levels for Costs," adopted by the Air Pollution Control Board on December 20, 1988. The cost analysis shall be based on the retrofit cost of the component if a retrofit is feasible. If the component cannot be retrofitted, then the following control option with the lower cost shall be used in the cost analysis:
 - 1) Component replacement with the lowest feasible cost BACT option.
 - 2) Enclosing the component seal and venting to a vapor recovery system.
 - b. Evidence of costs with written bids from vendors, published price lists, or other verifiable cost information. The potential emission reduction from the component retrofit/replacement shall be based on the ROC emissions over the previous 12

months. ROC emissions from a critical process unit shutdown shall be included if those emissions are associated with a critical leaking component. APCO-approved emission factors or source tests shall be used to quantify emissions.

29. Pursuant to Rule 74.10.H.1, any person subject to Rule 74.10 shall maintain an inspection log. The inspection log shall contain at least the following:
 - a. Location, type, description, and name or code of each leaking component inspected that cannot be immediately repaired, and name of associated operating unit.
 - b. For liquid leaks that cannot be immediately repaired: Date and time of leak detection and whether leak is major or minor.
 - c. For gaseous leaks that cannot be immediately repaired: Date and time of leak detection, date and time of leak measurement, analyzer reading (ppmv) of the leak, and whether the leak is major or minor.
 - d. Date that leak referenced in Rule 74.10.H.1.b or Rule 74.10.H.1.c is repaired to a leak-free condition, description of repair action, and date and emission level of re-check.
 - e. Identification of leak as critical if the component is critical.
 - f. Maintenance and calibration records of appropriate analyzer used in the EPA Method 21 measurements.
30. Pursuant to Rule 74.10.H.2, where a functional pressure relief has been detected, the operator shall record:
 - a. Location, operating unit identification, and date of detection.
 - b. Date of inspection of the pressure relief device after it was detected, and analyzer reading from EPA Method 21.
31. Pursuant to Rules 74.10.H.3 and 74.10.H.4, the inspection log shall be retained by the operator and shall be made available upon request to District personnel.
32. Pursuant to Rule 74.10.I.1, gaseous leaks from components shall be inspected or determined by EPA Method 21 by using an appropriate analyzer calibrated with methane. The calibration, maintenance, and operation of the appropriate analyzer shall follow the manufacturer's recommendations.

33. Pursuant to Rule 74.10.I.2, the ROC concentration, by weight, of process streams shall be measured by ASTM E168-88 (General Techniques of Infrared Qualitative Analysis), ASTM E169-87 (General Techniques of Ultraviolet Quantitative Analysis), or ASTM E260-85 (Gas Chromatography), or updated versions of these methods approved by EPA and published in the 40 CFR Part 60.
34. Pursuant to Rule 74.10.I.3, weight percentage of evaporated compounds of liquids shall be determined using ASTM Method D 86-82.
35. Pursuant to Rule 74.10.I.4, the API gravity of crude oil shall be determined using ASTM Method D287.
36. Pursuant to Rule 74.10.J, the failure of a person to meet any requirements of Rule 74.10 shall constitute a violation of Rule 74.10. Each leak exceeding the applicable maximum leak threshold in Attachment 1 of Rule 74.10 discovered by District personnel will be considered to be a violation.

M:\TITLEV\Attachments updated\7410(3-10-98).docx

Ventura County Air Pollution Control District
Rule 74.11.1 Applicable Requirements
Rule 74.11.1, Large Water Heaters and Small Boilers

Rule 74.11.1, "Large Water Heaters and Small Boilers"
Adopted 09/11/12, Federally Enforceable

Applicability:

This attachment applies to all natural gas-fired water heaters, boilers, steam generators or process heaters (units) with a rated heat input capacity greater than or equal to 75,000 BTU/hr and less than 1,000,000 BTU/hr at this stationary source installed after January 1, 2013 and to the future installation of any such unit at this stationary source. Note that units rated less than 1,000,000 BTU/hr are exempt from District permit requirements pursuant to Rule 23.C.1.

Conditions:

1. Pursuant to Rule 74.11.1.B.2, no person shall sell, offer for sale, or install in Ventura County any new unit with a rated heat input capacity of greater than or equal to 75,000 BTU/hr and less than or equal to 400,000 BTU/hr that does not meet the following criteria:
 - a. Oxides of nitrogen emissions shall not exceed 14 nanograms per joule of heat output (32.5 pounds per billion BTU), or 20 parts per million, and
 - b. The unit is certified in accordance with Rule 74.11.1.C.

The oxides of nitrogen emission standard required above (Condition No. 1.a) does not apply to units specifically designed to heat swimming pools, hot tubs, or spas. For such units, oxides of nitrogen emissions shall not exceed 40 nanograms per joule of heat output (93 pounds per billion BTU), or 55 parts per million.

2. Pursuant to Rule 74.11.1.B.4, no person shall sell, offer for sale, or install in Ventura County any new unit with a rated heat input capacity of greater than 400,000 BTU/hr and less than 1,000,000 BTU/hr that does not meet the following criteria:
 - a. Oxides of nitrogen emissions shall not exceed 20 parts per million and carbon monoxide emissions shall not exceed 400 parts per million, and
 - b. The unit is certified in accordance with Rule 74.11.1.C.
3. The permittee shall maintain a listing of manufacturer, brand name, model number, heat input rating, and installation date for each water heater, boiler, steam generator and

process heater, with a rated heat input capacity greater than or equal to 75,000 BTU/hr and less than 1,000,000 BTU/hr, at this stationary source. Permittee shall submit these identification records for all of these units to the District upon request.

4. On an annual basis, the permittee shall certify that all water heaters, boilers, steam generators and process heaters, with a rated heat input capacity greater than or equal to 75,000 BTU/hr and less than 1,000,000 BTU/hr, at this stationary source are complying with Rule 74.11.1. This annual certification shall include a formal survey identifying each unit and documentation of certification status (pursuant to Rule 74.11.1.C), as required.

M:\TITLEV\Attachments updated\7411.1 (9-11-12).docx

Ventura County Air Pollution Control District
Rule 74.22 Applicable Requirements
Rule 74.22, Natural Gas-Fired Fan-Type Central Furnaces

Rule 74.22, "Natural Gas-Fired Fan-Type Central Furnaces"
Adopted 11/09/93, Federally Enforceable

Applicability:

This attachment applies to all natural gas-fired, fan-type central furnaces at this stationary source installed after May 31, 1994 and to the future installation of any natural gas-fired, fan-type central furnaces at this stationary source. A fan-type central furnace is a self contained space heater providing for circulation of heated air at pressures other than atmospheric through ducts of more than 10 inches in length that has a rated heat input capacity of less than 175,000 BTU per hour and, for combination heating and cooling units, a rated cooling capacity of less than 65,000 BTU per hour. Natural gas-fired, fan-type central furnaces installed in manufactured housing (mobile homes) are exempt from Rule 74.22.

Conditions:

1. Pursuant to Rule 74.22.B, no person shall install, after May 31, 1994, any natural gas-fired fan-type central furnace:
 - a. with NO_x (oxides of nitrogen) emissions in excess of 40 nanograms per joule of heat output. (74.22.B.1)
 - b. unless it is certified and identified in accordance with Section C of Rule 74.22. (74.22.B.2)
2. Permittee shall maintain a listing of manufacturer, brand name, model number, and heat input rating for each natural gas-fired fan-type central furnace at this stationary source. Permittee shall submit these identification records for all of these furnaces to the District upon request.
3. On an annual basis, permittee shall certify that all natural gas-fired fan-type central furnaces at this stationary source are complying with Rule 74.22. This annual certification shall include a formal survey identifying each natural gas-fired fan-type central furnace; whether it was installed before or after May 31, 1994; and for those furnaces installed after May 31, 1994, information indicating that the certification is contained on the furnace nameplate, or that the furnace is included on a District-provided list of certified furnaces.

M:\TITLEV\Attachments updated\7422.docx

**Ventura County Air Pollution Control District
California Air Resources Board
Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities**

California Code of Regulations, Title 17, Division 3, Chapter 1, Subchapter 10 Climate Change, Article 4, Subarticle 13:

Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities, Effective date October 1, 2017

District enforceable only. The Ventura County APCD (VCAPCD) signed a Memorandum of Understanding (MOU) with the California ARB on June 12, 2018 to implement and enforce this regulation. Prior to June 12, 2018, this regulation was implemented and enforced only by California Air Resources Board (CARB). The regulation is not federally-enforceable.

Applicability:

This regulation applies to owners or operators of equipment and components listed in Section 95668 located within California, including California waters, that are associated with facilities in the sectors listed below, regardless of emissions level:

- (1) Onshore and offshore crude oil or natural gas production; and,
- (2) Crude oil, condensate, and produced water separation and storage; and,
- (3) Natural gas underground storage; and,
- (4) Natural gas gathering and boosting stations; and,
- (5) Natural gas processing plants; and,
- (6) Natural gas transmission compressor stations.

This regulation does not apply to the OCS Offshore Oil Platforms that the VCAPCD regulates because they are not in state territorial waters.

VCAPCD enforces this regulation through its existing permit system. As required below, facilities are required to register equipment with the California ARB on an initial and annual basis.

Conditions:

1. The facility shall be operated in compliance with all applicable requirements of Sections 95665 to 95677, Title 17, Division 3, Chapter 1, Subchapter 10 Climate Change, Article 4, Subarticle 13 California Code of Regulations, "Greenhouse Gas Emission Standards for Crude Oil and Natural Gas Facilities". This includes, but is not limited to, the following requirements.

2. Separator and tank systems shall comply with Section 95668(a). Note that the GHG Regulation defines a separator as a tank or pressure vessel for separating oil, water, condensate, and natural gas. In VCAPCD terminology, a “Wash Tank” is a “Separator” in the GHG Regulation. VCAPCD LACT Tanks, COST Tanks, and Produced / Waste Water Tanks are “Tanks” in the GHG Regulation. Note that VCAPCD Rule 71.1, “Crude Oil Production and Separation” is far more stringent than the GHG Regulation in terms of requiring vapor recovery systems for Separator and Tank Systems. Flash testing is not required for new and existing tanks equipped with vapor recovery systems required by Rule 71.1.
3. Circulation tanks for well stimulation treatments shall comply with Section 95668(b).
4. Reciprocating natural gas compressors shall comply with Section 95668(c).
5. Centrifugal natural gas compressors shall comply with Section 95668(d).
6. Natural gas powered pneumatic devices and pumps shall comply with Section 95668(e).
7. Liquid unloading of natural gas wells shall comply with Section 95668(f).
8. Well casing vents shall comply with Section 95668(g).
9. Natural gas underground storage facilities shall comply with the monitoring requirements of Section 95668(h).
10. The facility shall comply with the leak detection and repair requirements of Section 95669. Critical components at critical process units shall comply with Section 95670.
11. Vapor collection systems and vapor control devices shall comply with Section 95671. These requirements do not apply to existing vapor collection systems and vapor control devices that are required by VCAPCD Rule 71.1, Section B for storage tanks and Rule 71.1, Section C for produced gas.

The GHG Regulation defines “fuel gas system” and the VCAPCD considers it to be on-site combustion of natural gas in engines, boilers, heater treaters, steam generators, turbines, microturbines, glycol units, etc. Some oilfield facilities may sell gas to a party other than Southern California Gas (such as a nearby agricultural source). The VCAPCD considers these 3rd party gas sales to be a “sales gas system” in the GHG Regulation.

12. The facility shall comply with the record keeping requirements of Section 95672.
13. The facility shall comply with the reporting requirements of Section 95673.

14. The facility shall comply with the implementation requirements of Section 95674. The facility shall register equipment with the California Air Resources Board (ARB) on an initial basis as required by Section 95674(b)(2) and on an annual basis as required by Section 95674(b)(3).

The facility is not required to submit a permit application to the Ventura County APCD as a mechanism to comply with this regulation. This regulation, however, does not change the Ventura County APCD Rule 10 permitting requirements for new, modified, and replacement oil wells, gas wells, storage tanks, engines, loading racks, heaters, boilers, glycol units, flare, etc.

\\MATTILEV\Attachments updated\CARB GHG OIL GAS.docx

10. GENERAL REQUIREMENTS FOR SHORT-TERM ACTIVITIES (ATTACHMENTS)

The general requirements for short-term activities are broadly applicable requirements that apply to temporary activities at the facility (e.g., abrasive blasting, architectural coatings, degassing operations, etc.). These are activities occurring infrequently and for a short duration.

Requirements for short-term activities can normally be adequately addressed in the permit application with minimal or no reference to any specific emissions unit, provided that the scope of the requirement and the manner of its enforcement are clear.

As detailed in the Title V Permit Reissuance Application, general applicable requirements for short-term activities that apply to this facility were determined. The permit conditions associated with each requirement for a short-term activity are listed in an individual attachment. The attachment is identified with the label "Attachment (APCD Rule No.) ____" or "Attachment 40CFR61.M" in the lower left corner of each attachment.

Ventura County Air Pollution Control District
Rule 74.1 Applicable Requirements
Abrasive Blasting

Rule 74.1, "Abrasive Blasting"
Adopted 11/12/91, Federally Enforceable

Applicability:

This attachment applies to short term activities involving any abrasive blasting operation conducted at this facility. Abrasive blasting is the operation of cleaning or preparing a surface by forcibly propelling a stream of abrasive material against that surface. Abrasive materials subject to Rule 74.1 include, but are not limited to, sand, slag, steel shot, garnet or walnut shells.

Conditions:

1. Pursuant to Rule 74.1.B.1.a, all abrasive blasting operations shall be conducted within a permanent building, except for abrasive blasting operations conducted under one or more of the following conditions as detailed in Rule 74.1.B.1.b:
 - a. Steel or iron shot/grit is used exclusively
 - b. The item to be blasted exceeds eight feet in any dimension
 - c. The surface being blasted is situated at its permanent location or no further away from its permanent location than is necessary to allow the surface to be blasted
2. Pursuant to Rule 74.1.B.1.c, any abrasive blasting that is allowed to be conducted outside of a permanent building, and is not exclusively using steel or iron shot/grit, must use one of the following:
 - a. Wet abrasive blasting
 - b. Hydroblasting
 - c. Vacuum blasting
 - d. Dry blasting with California ARB certified abrasives
3. Abrasive blasting for pavement marking shall comply with the requirements of Rule 74.1.B.2.

4. Abrasive blasting of stucco and concrete shall comply with the requirements of Rule 74.1.B.3.
5. Packages or containers for abrasives certified in accordance with Section 92530 of the California Code of Regulations used for permissible outdoor blasting shall comply with the labeling requirements of Rule 74.1.B.4.
6. Abrasive blasting operations shall comply with the visible emission standards of Rule 74.1.C.1 and the nuisance prohibition of Rule 74.1.C.2. The visible emission evaluation of abrasive blasting operations shall be conducted in accordance with Section 92400 of the California Code of Regulations.
7. Permittee shall monitor each abrasive blasting operation to ensure that compliance with Rule 74.1 is being maintained. For each abrasive blasting operation conducted at the facility, permittee shall maintain records of the following information:
 - a. Date of operation
 - b. Type of abrasive blasting media used
 - c. Identity, size, and location of item blasted
 - d. Whether operation was conducted inside or outside a permanent building
 - e. California ARB certifications for abrasives used

These records shall be maintained at the facility and submitted to the District upon request.

Ventura County Air Pollution Control District
Rule 74.2 Applicable Requirements
Architectural Coatings

Rule 74.2, "Architectural Coatings"
Adopted 01/12/10, Federally Enforceable

Applicability:

This attachment applies to short term activities involving any person who supplies, sells, offers for sale, applies or solicits the application of any architectural coating at this stationary source. An architectural coating is a coating to be applied to stationary structures or their appurtenances at the site of installation, to portable buildings at the site of installation, to pavements, or to curbs. Coatings applied in shop applications or to nonstationary structures, such as airplanes, ships, boats, railcars and automobiles, are not considered to be architectural coatings for the purposes of this rule, nor are adhesives.

This attachment and Rule 74.2 do not apply to architectural coatings that are sold in a container with a volume of one liter (1.057 quart) or less and do not apply to any aerosol coating product.

Conditions:

1. Pursuant to Rule 74.2.B.1, the volatile organic compound (VOC) content of architectural coatings shall not exceed the following standards, as found in Table 2 of Rule 74.2.B.1, unless specifically exempted by Rule 74.2:
 - a. The VOC content of flat coatings shall not exceed 50 grams per liter of coating.
 - b. The VOC content of nonflat coatings shall not exceed 100 grams per liter of coating.
 - c. The VOC content of nonflat-high gloss coatings shall not exceed 150 grams per liter of coating.

Limits are expressed as VOC Regulatory (unless otherwise specified in Rule 74.2) thinned to the manufacturer's maximum recommendation, excluding colorant added to the tint bases. VOC Regulatory is defined in Rule 74.2.

2. Pursuant to Rule 74.2.B.1, the VOC content of specialty architectural coatings shall not exceed the VOC limits in the Table of Standards in Rule 74.2, unless specifically exempted by Rule 74.2.

Specifically, the VOC content of industrial maintenance coatings shall not exceed 250 grams per liter of coating.

Limits are expressed as VOC Regulatory (unless otherwise specified in Rule 74.2) thinned to the manufacturer's maximum recommendation, excluding colorant added to the tint bases. VOC Regulatory is defined in Rule 74.2.

3. Pursuant to Rule 74.2.B.4, all architectural coating containers used to apply the contents therein to a surface directly from the container by pouring, siphoning, brushing, rolling, padding, ragging or other means, shall be closed when not in use. These architectural coating containers include, but are not limited to, drums, buckets, cans, pails, trays or other application containers. Containers of any VOC-containing materials used for thinning and cleanup shall also be closed when not in use.
4. Pursuant to Rule 74.2.B.5, no person who applies or solicits the application of any architectural coating shall apply or solicit the application of any coating that is thinned to exceed the applicable VOC limit specified in the Tables in Subsection B.1.
5. Permittee shall conduct periodic facility inspections and an annual compliance certification of architectural coating operations to ensure that compliance with Rule 74.2 is being maintained. Permittee shall specify the usage of compliant coatings and shall maintain VOC records of coatings used at the stationary source. The VOC coating records shall be submitted to the District upon request.
6. The VOC content of architectural coatings, along with other specified physical and chemical properties, shall be measured using the testing procedures in Rule 74.2.G.

Ventura County Air Pollution Control District
Rule 74.4.D Applicable Requirements
Cutback Asphalt - Road Oils

Rule 74.4, "Cutback Asphalt"
Adopted 07/05/83, Federally-Enforceable

Applicability:

This attachment applies to short term activities involving the application of road oils for road, highway or street paving and maintenance. For the purpose of Rule 74.4, road oil shall be synonymous with slow cure asphalt.

Conditions:

1. Pursuant to Rule 74.4.D, road oils used for highway or street paving or maintenance applications shall contain no more than 0.5 percent of organic compounds which boil at less than 500°F as determined by ASTM D402.
2. Permittee shall maintain a test report of oil being proposed for usage in order to ensure that compliance with Rule 74.4.D is being maintained. Permittee shall maintain records of oil analyses at the facility and submit these records to the District upon request.

M:\TITLEV\Attachments updated\744D.docx

Ventura County Air Pollution Control District
Rule 74.16 Applicable Requirements
Oilfield Drilling Operations

Rule 74.16, "Oilfield Drilling Operations"
Adopted 01/08/91, Federally-Enforceable

Applicability:

This attachment applies to short term activities involving all oilfield drilling operations. Oilfield drilling operations are defined as activities powered by nonvehicular internal combustion engines for the purpose of drilling or redrilling oil wells, injection wells, or gas wells. For the purpose of Rule 74.16, drilling operations do not include any operations at any existing well where the derrick is a part of an oilwell production service unit, as defined in the California Vehicle Code. Rule 74.16 applies to drill rig engines over 50 HP including, but not limited to, engines supplying power to drawworks, rotary tables, mud pumps, mud mixers and auxiliary generators.

This attachment applies to an oil company, which Rule 74.16 defines as the person contracting the drilling rig and/or the person who applies for an Authority to Construct for the well. The APCD issues portable Permits to Operate to the owners of drilling rigs. If the drilling rig is registered with the California Air Resources Board Portable Equipment Registration Program (PERP), an APCD Permit to Operate is not required.

This permit does not authorize the operation of any non-vehicular engine of 50 BHP, or greater, for well drilling or workover operations. Prior to using such an engine, the engine owner shall obtain a Permit to Operate for the engine or shall use an engine that is registered with the California Air Resources Board PERP.

Conditions:

1. Pursuant to Rule 74.16.B.1, all drilling operations shall be powered by grid power, unless exempted by Rule 74.16.C.1. Grid power is defined as electricity conveyed by power lines connected physically and contractually to the Southern California Edison System, or any electricity generated by equipment permitted by the District and having permitted emissions commensurate with an emissions rate of not more than 1.0 pound of NO_x per megawatt-hour of electricity produced.
2. Pursuant to Rule 74.16.C.1, an oil company may petition the Air Pollution Control Officer for exemption from Rule 74.16.B.1 by submitting a cost evaluation for grid powered drilling. Best Available Control Technology cost guidelines shall be used to determine cost effectiveness. As detailed in APCD Rule 44, "Exemption Evaluation Fee", Rule 44.B.2 requires that any person requesting an exemption from Rule 74.16 that is based on a cost evaluation shall be assessed an evaluation fee of \$450.00.

3. Pursuant to Rule 74.16.B.2.a, if a drilling operation is exempt from Rule 74.16.B.1, NO_x emissions from drilling engines, or any exhaust stack of multiple engines permanently manifolded together, shall not exceed 515 ppmv corrected to 15% oxygen. As an alternate, pursuant to Rule 74.16.B.2.c, drilling engines certified by the manufacturer to emit 6.9 grams of NO_x per brake horsepower-hour or less based on a California ARB approved heavy duty offroad engine testing procedure shall be deemed in compliance with Rule 74.16.B.2.a, and shall not be subject to the annual source test requirements in Rule 74.16.B.2.b.

In order to comply with this condition, permittee shall ensure that the drilling rig utilized has a valid APCD Permit to Operate and that the drilling rig has demonstrated compliance with Rule 74.16.B.2.a in accordance with CARB Method 100 as detailed in Rule 74.16.E (Test Methods), or has demonstrated compliance with Rule 74.16.B.2.c. Alternatively, the permittee shall verify that the drilling rig is registered with the California Air Resources Board PERP.

4. In order to demonstrate compliance with Rule 74.16.B.2.a, the drilling rig company shall perform source testing on the drilling engine exhaust annually. Permittee shall obtain from the drilling rig company the most recent source test results for the exempt engines subject to Rule 74.16.B.2.a, or the engine manufacturer certification for engines subject to Rule 74.16.B.2.c. This information shall be made available on site and submitted to the District upon request.

This condition does not apply to drilling rig engines registered with the California Air Resources Board PERP.

5. Upon District request, the NO_x emissions from the drilling engine exhaust shall be measured using CARB Method 100, in accordance with Rule 74.16.E (Test Methods).
6. In order to demonstrate compliance with Rule 74.16.C.1, permittee shall maintain documentation on the cost analysis as verification to the grid power exemption. This documentation shall be submitted to the District upon request.

Ventura County Air Pollution Control District
Rule 74.26 Applicable Requirements
Crude Oil Storage Tank Degassing Operations

Rule 74.26, "Crude Oil Storage Tank Degassing Operations"
Adopted 11/08/94, Federally-Enforceable

Applicability:

This attachment applies to short term activities involving degassing of any aboveground crude oil or produced water storage tank that is equipped with a vapor recovery system and has a storage capacity greater than 2,000 barrels; or has a storage capacity of 2,000 barrels and stores a liquid having a modified Reid vapor pressure (mRVP) of 3.4 pounds per square inch (psi) absolute or greater. This attachment also applies to any external or internal floating roof crude oil tank that has a vapor space of 2,000 barrels or more when the tank's roof is resting on the tank's inner roof supports. Rule 74.26 does not apply to vessels rated and operated to contain normal working pressure of at least 15 psi gauge without vapor loss to the atmosphere.

Degassing is defined as the removal of organic vapors from a stationary storage tank for the purpose of cleaning, removing the tank, cleaning the tank's interior, or making repairs to the tank that would require the complete removal of product from the tank.

This permit does not authorize the operation of any air pollution control device for tank degassing operations. This includes, but is not limited to, a thermal or catalytic incinerator, a carbon adsorber, a condenser, or an internal combustion engine. Prior to using such a device, the owner of the air pollution control device shall obtain a Permit to Operate for the device.

Conditions:

1. Pursuant to Rule 74.26.B.1, no person shall conduct or allow the degassing of any storage tank subject to Rule 74.26, unless the emissions are controlled by one of the following options:
 - a. Liquid displacement into a vapor recovery system, flare, or fuel gas system (Rule 74.26.B.1.a). Liquid displacement is defined as the removal of ROC vapors from within a storage tank drained of liquid product by introducing into the tank a liquid having an ROC modified Reid vapor pressure (mRVP) of less than 0.5 psi absolute until at least 90 percent of the tank's vapor volume has been displaced, with the mRVP determined using ASTM Method D 323-82 conducted at 68 degrees Fahrenheit (Rule 74.26.F.10). or
 - b. An air pollution control device that has a vapor destruction and removal efficiency of at least 95 percent until the vapor concentration in (Rule 74.26.B.1.b):

1. Aboveground crude oil or produced water tanks equipped with a vapor recovery system, is less than 10 percent of the tank's initial vapor concentration determined immediately prior to the tank degassing, or less than 10,000 ppmv, measured as methane, or
2. Floating roof tanks, is less than 10,000 ppmv, measured as methane.

Fugitive emissions that do not qualify as a leak shall be allowed around tank openings such as a manhole during a tank degassing operation performed in compliance with Rule 74.26.

Pursuant to Rule 74.26.E.3, compliance with the above limits shall require that the tank vapor concentration remain at or below 10,000 ppmv for at least one hour as demonstrated by measuring the vapor concentration at least four times at 15-minute intervals. The monitoring instrument used to measure the vapor concentration shall meet the specifications of EPA Method 21.

2. Pursuant to Rule 74.26.B.2, any receiving vessel used during a tank cleaning operation shall either be bottom loaded or shall be loaded by submerged fill pipe. Any vapors emitted from such vessels during a tank degassing operation shall be controlled with an air pollution control device as required by Rule 74.26.B.1.b. As defined in Rule 74.26.F.14, a receiving vessel is a vessel used to receive liquids or sludge material removed from an ROC liquid storage tank during a tank degassing operation.
3. Pursuant to Rule 74.26.B.3, except during an emergency, the District Enforcement Section shall be notified verbally or in writing at least 48 hours prior to starting any tank degassing operation. Such notification shall include an identification of the tank(s) to be degassed and the air pollution control method employed. If a tank degassing operation was required due to an emergency, the District Enforcement Section shall be notified as soon as reasonably possible but no later than four hours after completion of the operation. An emergency is defined as an unplanned and unexpected event that, if not immediately attended to, presents a safety or public health hazard or an unreasonable financial burden.
4. In order to demonstrate compliance for air pollution control devices used to comply with Rule 74.26.B, operator shall record:
 - a. The vapor concentration in parts per million (ppm) and gas flow rate in cubic feet per minute (cfm) entering and exiting the device (except for a flare) upon beginning use of the device and every thirty minutes thereafter. The instrument used to measure vapor concentration shall meet the specifications of EPA Method 21, and

- b. The tank's vapor concentrations determined in accordance with Rule 74.26.E.3, and
 - c. If a refrigerated condenser is used, permittee shall record the condenser temperature in degrees Fahrenheit upon beginning use of the condenser and every thirty minutes thereafter. These records shall be maintained and shall be submitted to the District upon request.
5. Pursuant to Rule 74.26.D.3, any person claiming an exemption for a storage tank based on mRVP shall provide records that demonstrate that the liquid stored in the tank has a mRVP less than 3.4 psi absolute, as determined by ASTM Method D 323-82.
 6. Pursuant to Rule 74.26.E.2, methods for determining vapor destruction or removal efficiency include vapor flow through the pipes, measured using EPA Method 2A; and the vapor concentration entering and exiting the device, measured using EPA Method 25A. This testing shall be performed upon District request.
 7. Pursuant to Rule 74.26.E.3, the monitoring instrument used to measure the tank vapor concentration specified in Subsection B.1.b shall meet the specifications of EPA Method 21 and shall contain a probe inlet located one foot above the bottom of the tank or one foot above the surface of any sludge material on the bottom of the tank. For upright, cylindrical aboveground tanks, the probe inlet shall be (1) located at least 2 feet away from the inner surface of the tank wall and (2) if samples are withdrawn from a manhole, inserted in an opening of no more than one inch diameter on a flexible or inflexible material that is impermeable to reactive organic compound (ROC) vapors, secured over the manhole.
 8. In order to comply with the above conditions, permittee shall insure that any tank degassing subcontractor utilized has a valid APCD Permit to Operate for portable tank degassing emission control equipment and that the control equipment complies with Rule 74.26, in accordance with Rule 74.26.E (Test Methods) when necessary.
 9. Pursuant to Rule 74.26.C.2, the provisions of Section B of Rule 74.26 shall not apply to in-service tanks undergoing maintenance, including but not limited to repair of regulators, fittings, deck components, hatches, valves, flame arrestors, or compressors, or any leaks found pursuant to the operator inspection requirements in Rule 74.10, provided that (1) the operation will take no longer than 24 hours to complete and (2) the maintenance operation does not require the complete draining of product from the tank.

**Ventura County Air Pollution Control District
Applicable Requirements for Soil Aeration Operations
Rule 74.29, Soil Decontamination Operations**

**Rule 74.29, "Soil Decontamination Operations"
Adopted 04/08/08, Federally Enforceable**

Applicability:

This attachment applies to short-term activities involving soils that contain gasoline, diesel fuel, or jet fuel. Rule 74.29 does not apply to soil that contains only crude oil or was contaminated by a leaking storage tank used in an agricultural operation engaged in the growing of crops or the raising of fowl or animals.

Specifically, this attachment applies to the aeration of soil that contains gasoline, diesel fuel, or jet fuel. Aeration is defined as the exposure of excavated soil, containing diesel fuel, gasoline, or jet fuel, to the atmosphere without the use of air pollution control equipment or vapor extraction, bioremediation, or bioventing system.

Remediation equipment, such as a vapor extraction system, bioremediation system, or bioventing system, for contaminated soil requires an APCD permit. Rule 74.29 requirements for such remediation equipment would be addressed in another permit attachment, if applicable. As detailed in APCD Rule 23.F.23, any soil aeration project exempt from the soil aeration limit in Rule 74.29 pursuant to Subsection C.1 or C.2 of Rule 74.29 is exempt from the requirement to obtain a permit for the soil aeration project. Also, pursuant to APCD Rule 23.F.24, any soil remediation project where collected vapors are not emitted to the atmosphere by any means is exempt from the requirement to obtain a permit.

Conditions:

1. Pursuant to Rule 74.29.B.1.a, no person shall cause or allow the aeration of soil that contains gasoline, diesel fuel, or jet fuel if such aeration emits reactive organic compounds (ROC) as measured by a certified vapor analyzer, in excess of 50 parts per million by volume (ppmv) above background, as hexane, except nonrepeatable momentary readings. In determining compliance, a portion of soil measuring three inches in depth and no less than six inches in diameter shall be removed from the soil surface and the probe inlet shall be placed near the center of the resulting hole, level with the soil surface surrounding the hole.

For each soil decontamination operation where soil aeration occurs, the permittee shall determine compliance with Rule 74.29.B.1.a on a weekly basis as detailed above. A dated record of these measurements shall be maintained at the facility and submitted to the District upon request.

2. Pursuant to Rule 74.29.B.1.b, no person shall cause or allow the aeration of soil that contains gasoline, diesel fuel, or jet fuel if such aeration causes a nuisance, as defined in the California Health and Safety Code Section 41700 and APCD Rule 51, "Nuisance." In addition, offsite aeration is prohibited.
3. Pursuant to Rule 74.29.B.2, no person shall excavate an underground storage tank and/or transfer piping currently or previously used to store an applicable compound, or excavate or grade soil containing an applicable compound, unless ROC emissions are monitored with a certified organic vapor analyzer at least once every 15 minutes during the excavation period commencing at the beginning of excavation or grading. Soil with emission measurements in excess of 50 parts per million by volume (ppmv), as hexane, a shall be considered contaminated.

During excavation, all inactive exposed contaminated soil surfaces shall be treated with a vapor suppressant or covered with continuous heavy duty plastic sheeting (4 mil or greater) or other covering to minimize emissions of ROC to the atmosphere. Covering shall be in good condition, overlapped at the seams, and securely anchored to minimize headspace where vapors may accumulate.

4. Pursuant to Rule 74.29.B.5, the owner or operator of any applicable underground storage tank shall notify the District Compliance Division at least 24 hours prior to the beginning the excavation of the said storage tank and/or transfer piping.
5. Pursuant to Rule 74.29.B.6, contaminated soil in active storage piles shall be kept visibly moist by water spray, treated with a vapor suppressant, or covered with continuous heavy duty plastic sheeting (4 mil or greater) or other covering to minimize emissions of ROC to the atmosphere. Covering shall be in good condition, overlapped at the seams, and securely anchored to minimize headspace where vapors may accumulate. For any active storage pile, the surface area not covered by plastic sheeting or other covering shall not exceed 6,000 square feet. An "active" storage pile is defined as a worksite to which soil is currently being added or from which soil is being currently being removed. Activity must occur within one hour to be current.
6. Pursuant to Rule 74.29.B.7, contaminated soil in inactive storage piles shall be with covered with continuous heavy duty plastic sheeting (4 mil or greater) or other covering to minimize emissions to the atmosphere. The covering shall be in good condition, overlapped at the seams, and securely anchored to minimize headspace where vapors may accumulate.
7. Pursuant to Rule 74.29.B.8, if not removed within 30 days of excavation, on-site treatment to remove contamination from contaminated soil at an excavation or grading site shall be initiated. The treatment of contaminated soil shall be subject to all applicable District Rules and Regulations. This includes, but is not limited to,

compliance with Rule 10, "Permits Required," and Rule 51, "Nuisance."

8. Pursuant to Rule 74.29.B.9, trucks used to transport contaminated soil must meet the following requirements:
 - a. The truck and trailer shall be tarped prior to leaving the site. Contaminated material shall not be visible beyond the tarp and shall not extend above the sides or rear of the truck or trailer; and
 - b. The exterior of the truck, trailer and tires shall be cleaned prior to leaving the site.
9. Pursuant to Rule 74.29.C.2, the soil aeration requirements of Rule 74.29.B.1.a shall not apply to:
 - a. Soil excavation activities necessary for the removal of in-situ soil such as in the removal of an underground storage tank, pipe or piping system, provided the exposed soil is covered as specified in Condition No. 6 while inactive; or
 - b. Soil moving, loading, or transport activities performed for the sole purpose of complying with local, state, or federal laws, provided the soil is handled in accordance with such laws; or
 - c. Soil excavation or handling occurring as a result of an emergency as declared by an authorized health officer, agricultural commissioner, fire protection officer, or other authorized agency officer. Whenever possible, the District Compliance Division shall be notified prior to commencing such excavation; or
 - d. Any soil aeration project involving less than 1 cubic yard of contaminated soil; or
 - e. Situations where the soil contamination which resulted from a spill or release of less than five (5) gallons of diesel fuel, jet fuel, or gasoline; or
 - f. Contaminated soil used as daily cover at permitted Class III Solid Waste Disposal Sites if such soils do not have a gasoline concentration exceeding 100 parts per million by weight (ppmw) or a diesel fuel concentration exceeding 1,000 ppmw, as determined by the method specified in Rule 74.29.F.1. Daily cover is defined as soil that is applied on a daily basis or less frequently as a covering over landfill waste.

The permittee shall maintain records of the gasoline concentration and diesel fuel concentration of any contaminated soil used as daily cover that need to qualify for this exemption.

10. Pursuant to Rule 74.29.F.1, the percent by weight of contaminant in soil samples shall be determined by EPA Method 8015B. Samples shall be introduced using Method 5035 (Purge and Trap) and shall be taken in accordance with the Los Angeles Regional Water Quality Control Board's guidelines for contaminated soil sampling. Standards shall be the same as the contaminant believed to be in the soil. If the soil is contaminated with methanol 85 (M85) the standard used shall be M85.
11. Pursuant to Rule 74.29.F.3, the ROC concentration measurements required in Subsections B.1 and B.2 of the rule (Condition Nos. 1 – 3 above) shall be made using an organic vapor analyzer certified according to the requirements of EPA Method 21.
12. Pursuant to Rule 74.29.D, for any soil aeration project subject to Rule 74.29, the permittee shall record each date that the soil was disturbed and the quantity of soil disturbed on each date. These records shall be maintained at the facility and submitted to the District upon request.
13. For any soil decontamination project subject to Rule 74.29, other than a soil aeration project, the following information shall be made available to the District upon request:
 - a. All dates that soil was disturbed and the quantity of soil disturbed on each date.
 - b. Reasons for excavation or grading.
 - c. Cause of VOC soil contamination and history of the site.
 - d. Description of tanks or piping associated with the soil contamination.
 - e. Description of mitigation measures employed for dust, odors and ROC emissions.
 - f. Details of treatment and/or disposal of ROC contaminated soil, including the ultimate receptor.
 - g. Description of monitoring equipment and techniques.
 - h. All ROC emission measurements shall be recorded on a continuous permanent strip-chart or in a format approved by the Air Pollution Control Officer (APCO).
 - i. A map showing the facility layout, property line, and surrounding area up to 2500 feet away, and including any schools, residential areas or other sensitive receptors such as hospitals or locations where children or elderly people live or work.
14. The permittee shall monitor each soil aeration operation or underground gasoline storage tank excavation operation to ensure that compliance with Rule 74.29.B.1 and/or

74.29.B.2 is being maintained. This monitoring requirement shall include ensuring that proper operation requirements are being met and shall include the recordkeeping required above.

M:\TITLEV\Attachments updated\7429N3(12-07-2017).docx

11. GENERAL PERMIT CONDITIONS

This section contains general Part 70 permit conditions and general APCD permit to operate conditions. The general Part 70 permit conditions are associated with general federal requirements that apply to all Title V facilities. These conditions are based on APCD Rules 8, 30, 32, and 33, and 40 CFR Part 70.

The general permit to operate conditions are associated with general District requirements that apply to all operating Title V facilities. These conditions are based on APCD Rules 19, 20, 22, and 27.

M:\TITLEV\Attachments updated\PERMIT11.docx

**Ventura County Air Pollution Control District
General Part 70 Permit Conditions**

1. The permittee shall comply with all federally-enforceable conditions of the Part 70 permit. Any permit noncompliance constitutes a violation of the federal Clean Air Act and is grounds for enforcement action; for permit termination, revocation and reissuance, or modification; or for denial of an application for reissuance of the permit. (40 CFR 70.6(a)(6)(i), APCD Rule 33.3.B.1)
2. The permittee shall continue to comply with all the applicable requirements with which the company has certified that it is already in compliance. The permittee shall comply in a timely manner with applicable requirements that become effective during the permit term of this permit.
3. The permittee shall promptly report deviations from Part 70 permit requirements, including those attributable to upset conditions as defined in the Part 70 permit, the probable cause of the deviations, and any corrective actions or preventive measures taken. Promptly is defined as no later than four (4) hours after its detection by such owner or operator, or his agents or employees. (40 CFR 70.6(a)(3)(iii)(B), APCD Rule 33.3.A.3, APCD Rule 32.B.1)
4. The need to halt or reduce activity is not a defense. It shall not be a defense for a permittee in an enforcement action that it would be necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of this Part 70 permit. (40 CFR 70.6(a)(6)(ii), APCD Rule 33.3.B.2)
5. All applicable records, monitoring data, and support information shall be maintained for a period of at least 5 years from the date of the monitoring sample, measurement, report, or application. Support information includes all calibration and maintenance records and all original strip chart recordings for continuous monitoring instrumentation, and copies of all reports required by the Part 70 permit. All applicable reports shall be submitted to the District every 6 months and shall be certified by a responsible official. Such reports shall identify any deviations from Part 70 permit conditions. (40 CFR 70.6(a)(3)(ii)(B), 40 CFR 70.6(a)(3)(iii)(A), APCD Rule 33.3.A.3)
6. The permittee shall furnish to the District, within a reasonable time, any information that the District may request in writing to determine whether cause exists for modifying, revoking and reissuing, or terminating the Part 70 permit or to determine compliance with the Part 70 permit. Upon request, the permittee shall also furnish to the District copies of records required to be kept by the Part 70 permit or, for information claimed to be confidential, the permittee may furnish such records directly to the Administrator of the EPA along with a claim of confidentiality. (40 CFR 70.6(a)(6)(v), APCD Rule 33.3.B.5)

7. Upon presentation of credentials and other documents as may be required by law, the permittee shall allow the District or an authorized representative to perform the following:
 - a. Enter upon the permittee's premises where a Part 70 source is located or emissions-related activity is conducted, or where records must be kept under the conditions of the Part 70 permit;
 - b. Have access to and copy, at reasonable times, any records that must be kept under the conditions of the Part 70 permit;
 - c. Inspect at reasonable times any facilities, equipment (including monitoring and air pollution control equipment), practices, or operations regulated or required under the Part 70 permit; and
 - d. As authorized by the federal Clean Air Act, sample or monitor at reasonable times substances or parameters for the purpose of assuring compliance with the Part 70 permit or applicable requirements.

(40 CFR 70.6(c)(2), APCD Rule 8, APCD Rule 33.3.B.7)

8. The Part 70 permit may be modified, revoked, reopened, reissued, or terminated for cause. The filing of a request by the permittee for a permit modification, revocation and reissuance, or termination, or of a notification of planned changes or anticipated noncompliance does not stay any permit condition. (40 CFR 70.6(a)(6)(iii), APCD Rule 33.3.B.3)
9. A Part 70 permit shall be reopened under the following conditions:
 - a. Additional applicable requirements under the federal Clean Air Act become applicable to the facility with a remaining Part 70 permit term of 3 or more years. Such a reopening shall be completed not later than 18 months after promulgation of the applicable requirement. No such reopening is required if the effective date of the requirement is later than the date on which the Part 70 permit is due to expire, unless the original Part 70 permit or any of its terms and conditions has been extended pursuant to APCD Rule 33.6.D;
 - b. Additional requirements (including excess emissions requirements) become applicable to an affected source under the acid rain program. Upon approval by the Administrator of the EPA, excess emissions offset plans shall be deemed to be incorporated into the Part 70 permit;

- c. The District or EPA determines that the Part 70 permit contains a material mistake or that inaccurate statements were made in establishing the emissions standards or other terms or conditions of the Part 70 permit; or
- d. The Administrator of the EPA or the District determines that the Part 70 permit must be revised or revoked to assure compliance with the applicable requirements.

(40 CFR 70.7(f), APCD Rule 33.8.A)

- 10. All fees required by District Regulation III, Fees, shall be paid on a timely basis as requested by the District. Notwithstanding the term of the Part 70 permit, if the permittee fails to pay the annual renewal fees required pursuant to APCD Rule 42.H within the time period specified in APCD Rule 30, the Part 70 permit will be void. (40 CFR 70.6(a)(7), APCD Rule 30, APCD Rule 33.3.B.6)
- 11. The Part 70 permit does not convey any property rights of any sort, or any exclusive privilege. (40 CFR 70.6(a)(6)(iv), APCD Rule 33.3.B.4)
- 12. The provisions of this Part 70 permit shall be severable, and in the event of any challenge to any portion of the permit, or if any portion is held invalid, the remaining permit conditions shall remain valid and in force. (40 CFR 70.6(a)(5), APCD Rule 33.3.B.8)
- 13. An application for reissuance of this Part 70 Permit shall be submitted no more than 18 months prior to the expiration date and no less than 6 months prior to the expiration date as stated on this permit. The application shall be subject to the same procedural requirements, including those for public participation and EPA review, that apply to initial Part 70 permit issuance. (40 CFR 70.5(a)(1)(iii), 40 CFR 70.7(c)(1)(i), APCD Rule 33.6.B)
- 14. Any Part 70 application and any document, including reports, schedule of compliance progress reports, and compliance certification, required by this Part 70 permit shall be certified by a responsible official. The certification shall state that, based on information and belief formed after a reasonable inquiry, the statements and information in the document are true, accurate, and complete (40 CFR 70.5(d), APCD Rule 33.9.C)
- 15. Permittee must submit certification of compliance with all applicable requirements and all Part 70 permit conditions. A compliance certification shall be submitted with any Part 70 permit application and annually, on the anniversary date of the Part 70 permit, or on a more frequent schedule if required by an applicable requirement or permit condition.

This compliance certification shall identify each applicable requirement or condition of the Part 70 permit, the compliance status of the stationary source, whether the compliance

was continuous or intermittent since the last certification, and the method(s) used to determine compliance. In addition, the certification shall indicate the stationary source's compliance status with any applicable enhanced monitoring and compliance certification requirement of the federal Clean Air Act. A copy of each compliance certification shall be submitted to EPA Region IX. (40 CFR 70.5(c)(9), 40 CFR 70.6(c)(5), APCD Rule 33.3.A.9, APCD Rule 33.9.B)

M:\TITLEV\Attachments updated\PART70GN (09-26-17).docx

**Ventura County Air Pollution Control District
General Permit to Operate Conditions**

1. Within 30 days after receipt of a permit to operate, the permittee may petition the Hearing Board, in writing, to review any new or modified condition on the permit. (APCD Rule 22)
2. This permit to operate, or a copy, shall be posted reasonably close to the subject equipment and shall be readily accessible to inspection personnel from the District. Posting a copy of the "Permitted Equipment and Applicable Requirements Table" contained in Section No. 2 will fulfill this requirement if the entire permit to operate is readily available at another location at the stationary source. (APCD Rule 19)
3. This permit to operate is not transferable from one location to another unless the equipment is specifically listed as being portable. (APCD Rule 20)
4. If, within a reasonable amount of time, any permittee refuses to furnish information requested by the District, the District may suspend this permit to operate. The permittee will be informed, in writing, of the permit suspension and the reasons for the suspension. (APCD Rule 27)

M:\TITLEV\Attachments updated\POGNCN.docx

**Ventura County Air Pollution Control District
Permit Shield - New Source Performance Standards
Part 70 Permit No. 00012**

40 CFR Part 60, Subpart J, “Standards of Performance for Petroleum Refineries”

40 CFR Part 60, Subpart UU, “Standards of Performance for Asphalt Processing and Asphalt Roofing Manufacture”

40 CFR Part 60, Subpart GGG, “Standards of Performance for Equipment Leaks of VOC in Petroleum Refineries”

40 CFR Part 60, Subpart QQQ, “Standards of Performance for VOC Emissions From Petroleum Refinery Wastewater Systems”

Permit Shield:

The New Source Performance Standards listed above have been reviewed and it has been determined that they are not applicable to this stationary source. Subpart J, Subpart GGG, and Subpart QQQ apply to affected facilities located at petroleum refineries. Subpart UU applies to affected facilities at asphalt processing plants, petroleum refineries, and asphalt roofing plants. This stationary source is not a petroleum refinery, asphalt roofing plant, or asphalt processing plant as defined in these New Source Performance Standards, and therefore these standards do not apply to this stationary source.

This stationary source is primarily a crude oil production facility. Steam and petroleum diluent are injected into heavy crude oil wells. The wells then produce a mixture of heavy crude oil, natural gas, diluent, and water. The mixture is initially separated by gravity, aided by heat. In order to recover the diluent, final separation is done in an atmospheric distillation tower.

The heavy crude oil is then sold as various grades of asphalt, and the diluent is recycled back into the oil wells. To balance the process on a seasonal basis, diluent is sold or purchased as necessary.

M:\TITLE\TV Permits\PO0012\Permit IV\Shield 1.doc

**Ventura County Air Pollution Control District
Permit Shield - New Source Performance Standards
Part 70 Permit No. 00012**

40 CFR Part 60, Subpart Dc, “Standards of Performance for Small Industrial - Commercial - Institutional Steam Generating Units”

Permit Shield:

The New Source Performance Standard listed above has been reviewed and it has been determined that it is not applicable to this stationary source. The following discussion details the determination of this permit shield for specific emission units at the stationary source. All of the units below burn natural gas as the primary fuel and burn fuel oil only during natural gas curtailment.

Six (6) 20.0 MMBTU/Hr Steam Generators (Unit Nos. 0, 1, 2, 3, 4, 5)

Five of these six steam generators were originally constructed prior to June 9, 1989. Authority to Construct No. 0010-100, issued on March 25, 1991, allowed for modifications to each of these steam generators to meet the emission limitations of Rule 74.15, “Boilers, Steam Generators, and Process Heaters”. Pursuant to 40 CFR Part 60.14.e.5, this change did not fit the definition of a modification subject to New Source Performance Standards since this was “the addition or use of any system or device whose primary function is the reduction of air pollutants.” The 20 MMBTU/hr Steam Generator No. 0 was installed after July 9, 1989; however, the unit operates on natural gas or a mixture of natural gas and produced gas. There are no applicable requirements in the Subpart for units operated on natural gas. This includes recordkeeping requirements.

One (1) 20.0 MMBTU/Hr Erie City Boiler

This boiler was originally constructed prior to June 9, 1989. Authority to Construct No. 0012-110, issued on August 13, 1990, allowed for modifications to this boiler to meet the emission limitations of Rule 74.15, “Boilers, Steam Generators, and Process Heaters”. Pursuant to 40 CFR Part 60.14.e.5, this change did not fit the definition of a modification subject to New Source Performance Standards since this was “the addition or use of any system or device whose primary function is the reduction of air pollutants.”

One (1) 20.0 MMBTU/Hr Natco Crude Oil Heater

This crude oil heater was originally constructed after June 9, 1989. Authority to Construct No. 0012-110, issued on August 13, 1990, allowed for the installation of this unit as a replacement for two existing units as a strategy to meet the emission limitations of Rule 74.15, “Boilers, Steam Generators, and Process Heaters”. The Natco Crude Oil Heater does not fit the definition of a steam generating unit as detailed in 40 CFR Part 60.41c. This unit does not heat water or any other heat transfer medium. Nor is it a process heater that heats a material to initiate or

promote a chemical reaction. It is, rather, a process heater that heats a mixture of heavy crude oil and diluent to promote their physical separation.

M:\TITLE\TV Permits\PO0012\Permit V\Shield 2-rev321.docx

**Ventura County Air Pollution Control District
Standards of Performance (NSPS) for
Crude Oil and Natural Gas Production, Transmission and Distribution**

40 CFR Part 60, Subpart OOOO, “Standards of Performance (NSPS) for Crude Oil and Natural Gas Production, Transmission and Distribution for which Construction, Modification or Reconstruction Commenced After August 23, 2011, and on or before September 18, 2015”

Applicability:

This NSPS was replaced by 40 CFR Part 60, Subpart OOOOa that now applies to affected oil and gas facilities after September 18, 2015.

This NSPS applies to all well completions, pneumatic controllers, equipment leaks from natural gas processing plants, reciprocating compressors, centrifugal compressors and storage vessels which are constructed, modified or reconstructed after August 23, 2011, and on or before September 18, 2015, as discussed in more detail below. Well completions subject to the NSPS are limited to the flowback period following hydraulic fracturing operations at an applicable gas well. These applicable completions include those conducted at newly drilled and fractured gas wells, as well as completions conducted following refracturing operations that may occur at various times over the life of the gas well. When a gas well is refractured, the applicability of this NSPS does not by itself trigger applicability beyond the well head to other ancillary components that may be at the well site such as existing storage vessels, compressors, pneumatic controllers, process vessels, separators, dehydrators or any other components or apparatus. Note that the NSPS does not apply to gas wells located on offshore oil platforms in Ventura County. This document summarizes the requirements of the NSPS and is not intended to supersede or conflict with the requirements of the NSPS.

Note that the issuance of this NSPS now includes, incorporates, and / or revises the requirements of 40 CFR Part 60 Subpart KKK, “Standards of Performance for Equipment Leaks of VOC From Onshore Natural Gas Processing Plants”, and 40 CFR Part 60 Subpart LLL, “Standards of Performance for Onshore Natural Gas Processing: SO₂ Emissions”. These NSPS now each have sunset dates of August 23, 2011 and their requirements are now contained in 40 CFR Part 60, Subpart OOOO, “Standards of Performance (NSPS) for Crude Oil and Natural Gas Production, Transmission and Distribution”.

Conditions:

1. Gas wells undergoing hydraulic fracturing subject to this NSPS shall comply with Section 60.5375. A gas well or natural gas well is defined as an onshore well drilled principally for production of natural gas. The NSPS requires the use of reduced emissions completions (REC) also known as green completions.

The drilling of all new oil wells and all new gas wells requires a Ventura County APCD Authority to Construct. In addition, an Authority to Construct shall be obtained prior to refracturing an existing gas well.

2. Centrifugal compressors subject to this NSPS shall comply with Section 60.5380. A centrifugal compressor is defined as any machine for raising the pressure of a natural gas by drawing in low pressure natural gas and discharging significantly higher pressure natural gas by means of mechanical rotating vanes or impellers. Screw, sliding vane, and liquid ring compressors are not centrifugal compressors as defined in this NSPS. The NSPS requires the operators of affected centrifugal compressors to reduce VOC emissions from each centrifugal compressor wet seal fluid degassing system by 95.0 percent or greater. Compressors located past the point of custody transfer in the gas transmission and storage segments are not covered by this NSPS. A compressor located at a well site, or an adjacent well site and servicing more than one well site, is not covered by this NSPS.

The Ventura County APCD does not require permits for natural gas compressors, but does require permits for an internal combustion engine (in lieu of an electric motor) powering a natural gas compressor (Rule 23.F.18). Therefore, this condition authorizes the installation of the equipment necessary to comply with these centrifugal compressor requirements provided that the permittee comply with all the requirements of Section 60.5380, including the required notification, recordkeeping and reporting requirements.

3. Reciprocating compressors subject to this NSPS shall comply with Section 60.5385. A reciprocating compressor is defined as a piece of equipment that increases the pressure of a process gas by positive displacement, employing linear movement of a drive shaft. The NSPS requires the operators of affected reciprocating compressors to replace the rod packing every 26,000 hours or 36 months from the date of initial startup of the reciprocating compressor affected facility. Compressors located past the point of custody transfer in the gas transmission and storage segments are not covered by this NSPS. A compressor located at a well site, or an adjacent well site and servicing more than one well site, is not covered by this NSPS.

The Ventura County APCD does not require permits for natural gas compressors, but does require permits for an internal combustion engine (in lieu of an electric motor) powering a natural gas compressor (Rule 23.F.18). Therefore, this condition authorizes the work necessary to comply with these reciprocating compressor requirements provided that the permittee comply with all the requirements of Section 60.5385, including the required notification, recordkeeping and reporting requirements.

4. Pneumatic controllers subject to this NSPS shall comply with Section 60.5390. A pneumatic controller is defined as an automated instrument used for maintaining a

process condition such as liquid level, pressure, delta-pressure and temperature. The requirements apply to natural gas-driven pneumatic controllers located (a) in the oil production segment between the wellhead and the point of custody transfer to an oil pipeline; or (b) in the natural gas production segment between the wellhead and the point at which the gas enters the transmission and storage segment. This NSPS requires each pneumatic controller affected facility at a natural gas processing plant to have a natural gas bleed rate of zero standard cubic feet per hour. Each pneumatic controller affected facility between the wellhead and a natural gas processing plant, or between the wellhead and the point of custody transfer to an oil pipeline, must have a natural gas bleed rate of less than or equal to 6 standard cubic feet per hour. Note that a natural gas processing plant is defined as any processing site engaged in the extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both. A Joule-Thompson valve, a dew point suppression valve, or an isolated or stand-alone Joule-Thompson skid is not a natural gas processing plant.

The Ventura County APCD does not require permits for the installation and operation of pneumatic controllers and other components such as valves and flanges. Therefore, this condition authorizes the work necessary to comply with these pneumatic controller requirements provided that the permittee comply with all the requirements of Section 60.5390, including the required notification, recordkeeping and reporting requirements.

5. Storage vessels subject to this NSPS shall comply with Section 60.5395. A storage vessel is defined as a unit that is constructed primarily of nonearthen materials (such as wood, concrete, steel, fiberglass, or plastic) which provides structural support and is designed to contain an accumulation of liquids or other materials. Note that pressure vessels designed to operate in excess of 204.9 kilopascals (29.7 psi) and without emissions to the atmosphere are not considered to be storage vessels. Also, process vessels such as surge control vessels, bottoms receivers, and knockout vessels are not considered to be process vessels.

The NSPS requires that individual storage vessels with VOC emissions equal to or greater than 6 tons per year achieve at least 95.0 percent reduction in VOC emissions. These requirements do not apply to storage vessels subject to and controlled in accordance with the requirements for storage vessels in 40 CFR Part 60, Subpart Kb, or 40 CFR Part 63, Subparts G, CC, HH, or WW.

The Ventura County APCD does require permits for the installation and operation of storage vessels such as crude oil storage tanks, wash tanks, and produced water storage tanks. In addition, these tanks must comply with the vapor recovery requirements of Rule 71.1, "Crude Oil Production and Separation". If a tank that complies with Rule 71.1 has VOC emissions of 6 tons per year or more, the permittee shall apply for, and obtain, an APCD Authority to Construct for the equipment necessary to comply with Section 60.5395 of the NSPS.

6. All process units, except compressors, located at an onshore natural gas processing plant subject to this NSPS shall comply with Section 60.5400. A process unit means components assembled for the extraction of natural gas liquids from field gas, the fractionation of the liquids into natural gas products or other operations associated with the processing of natural gas products.

The NSPS requires a leak detection and repair program for components such as pressure relief devices, pumps and valves that reflects the procedures and leak thresholds established in 40 CFR Part 60, Subpart VVa, the NSPS for Equipment Leaks of VOC in the Synthetic Organic Chemicals Manufacturing Industry (that is, this NSPS OOOO references out to NSPS VVa). For certain components, a leak is defined as 500 ppm or greater and a first attempt at a repair must be made no later than 5 calendar days after a leak is detected.

The Ventura County APCD does not require permits for the installation and operation of components such as pressure relief devices, pumps, valves and flanges. Therefore, this condition authorizes any work necessary to comply with these leak detection and repair requirements provided that the permittee comply with all the requirements of Section 60.5400, including the required notification, recordkeeping and reporting requirements. Any onshore natural gas processing plant at this facility subject to this NSPS will be specifically addressed elsewhere in this permit, as applicable.

7. Sweetening units at onshore natural gas processing plants subject to this NSPS shall comply with Section 60.5405. A sweetening unit is defined as a process device that removes hydrogen sulfide and / or carbon dioxide from the sour natural gas stream. To qualify as a sweetening unit, there must be sulfur recovery technology with a liquid sulfur accumulation rate. These requirements do not apply to sweetening units located on offshore oil platforms in Ventura County. The requirements also do not apply to devices that remove hydrogen sulfide or carbon dioxide that use replaceable media or units that use membrane separation technology.

The NSPS requires that the sweetening unit achieve a minimum SO₂ reduction efficiency that varies from approximately 74.0% to 99.9% depending on the hydrogen sulfide content of the acid gas and the sulfur feed rate.

The Ventura County APCD does require an Authority to Construct for the installation of a sweetening unit at both onshore natural gas plants and offshore natural gas plants. Any sweetening unit at this facility subject to this NSPS will be specifically addressed elsewhere in this permit, as applicable.

**Ventura County Air Pollution Control District
Standards of Performance (NSPS) for
Crude Oil and Natural Gas Facilities**

40 CFR Part 60, Subpart OOOOa, “Standards of Performance for Crude Oil and Natural Gas Facilities for which Construction, Modification or Reconstruction Commenced After September 18, 2015”

Applicability:

This NSPS establishes emission standards and compliance schedules for the control of the pollutant greenhouse gases (GHG). The greenhouse gas standard in this NSPS is in the form of a limitation on emissions of methane from affected facilities in the crude oil and natural gas source category that commence construction, modification, or reconstruction after September 18, 2015. This NSPS also establishes emission standards and compliance schedules for the control of volatile organic compounds (VOC) and sulfur dioxide (SO₂) emissions from affected facilities in the crude oil and natural gas source category that commence construction, modification or reconstruction after September 18, 2015. The effective date of the NSPS is August 2, 2016.

This NSPS applies to all onshore well completions, centrifugal compressors, reciprocating compressors, pneumatic controllers, storage vessels, process units for the extraction or fractionation of natural gas liquids from field gas, sweetening units, pneumatic pumps, and fugitive emissions from well sites and compressor stations which are constructed, modified or reconstructed after September 18, 2015, as discussed in more detail below. Note that this NSPS does not apply to offshore oil platforms in Ventura County.

Well completions subject to the NSPS are limited to the flowback period following hydraulic fracturing operations at an applicable oil or gas well. These applicable well completions include those conducted at newly drilled and fractured wells, as well as completions conducted following refracturing operations that may occur at various times over the life of the well.

Note that the issuance of this NSPS now includes, incorporates, and / or revises the requirements of 40 CFR Part 60, Subpart OOOO, “Standards of Performance (NSPS) for Crude Oil and Natural Gas Production, Transmission and Distribution”. 40 CFR Part 60, Subpart OOOO now has an effective date of August 23, 2011 to September 18, 2015 and its requirements are now contained in 40 CFR Part 60, Subpart OOOOa. This document summarizes the requirements of the NSPS and is not intended to supersede or conflict with the requirements of the NSPS.

Conditions:

1. Wells undergoing hydraulic fracturing or hydraulic refracturing subject to this NSPS shall comply with Section 60.5375a. A well is defined as an onshore well drilled for the purpose of producing oil or natural gas, or a well into which fluids are injected. During

the flowback period following hydraulic fracturing or refracturing, the NSPS requires the recovery of flowback liquids and the control of flowback gas. Note that the NSPS has specific requirements for wildcat wells and delineation wells, non-wildcat low pressure gas wells or non-delineation low pressure gas wells, and wells with less than 300 scf of gas per stock tank barrel of oil produced.

The drilling of all new oil wells and all new gas wells requires a Ventura County APCD Authority to Construct. In addition, an Authority to Construct shall be obtained prior to refracturing an existing oil or gas well.

2. Centrifugal compressors subject to this NSPS shall comply with Section 60.5380a. A centrifugal compressor is defined as any machine for raising the pressure of a natural gas by drawing in low pressure natural gas and discharging significantly higher pressure natural gas by means of mechanical rotating vanes or impellers. Screw, sliding vane, and liquid ring compressors are not centrifugal compressors as defined in this NSPS. The NSPS requires the operators of affected centrifugal compressors to reduce methane and VOC emissions from each centrifugal compressor wet seal fluid degassing system by 95.0 percent or greater. Compressors located at or past the point of custody transfer are not covered by this NSPS. A centrifugal compressor located at a well site, or an adjacent well site and servicing more than one well site, is not an affected facility under this NSPS.

The Ventura County APCD does not require permits for natural gas compressors, but does require permits for an internal combustion engine (in lieu of an electric motor) powering a natural gas compressor (Rule 23.F.18). Therefore, this condition authorizes the installation of the equipment necessary to comply with these centrifugal compressor requirements provided that the permittee comply with all the requirements of Section 60.5380a, including the required notification, recordkeeping and reporting requirements.

3. Reciprocating compressors subject to this NSPS shall comply with Section 60.5385a. A reciprocating compressor is defined as a piece of equipment that increases the pressure of a process gas by positive displacement, employing linear movement of a drive shaft. The NSPS requires the operators of affected reciprocating compressors to replace the rod packing every 26,000 hours or 36 months from the date of initial startup, or last rod packing replacement, of the reciprocating compressor affected facility. As an alternative to rod packing replacement, the NSPS requires that operators collect the methane and VOC emissions from the rod packing using a rod packing emissions collection system that operates under negative pressure and route the rod packing emissions to a process through a closed vent system. Compressors located at or past the point of custody transfer are not covered by this NSPS. A compressor located at a well site, or an adjacent well site and servicing more than one well site, is not an affected facility under this NSPS.

The Ventura County APCD does not require permits for natural gas compressors, but does require permits for an internal combustion engine (in lieu of an electric motor) powering a natural gas compressor (Rule 23.F.18). Therefore, this condition authorizes the work necessary to comply with these reciprocating compressor requirements provided that the permittee comply with all the requirements of Section 60.5385a, including the required notification, recordkeeping and reporting requirements.

4. Pneumatic controllers subject to this NSPS shall comply with Section 60.5390a. A pneumatic controller is defined as an automated instrument used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. This NSPS requires each pneumatic controller affected facility at a natural gas processing plant to have a natural gas bleed rate of zero standard cubic feet per hour. Each pneumatic controller affected facility, at a location other than at a natural gas processing plant, must have a natural gas bleed rate of less than or equal to 6 standard cubic feet per hour. Note that a natural gas processing plant is defined as any processing site engaged in the extraction of natural gas liquids from field gas, fractionation of mixed natural gas liquids to natural gas products, or both. A Joule-Thompson valve, a dew point suppression valve, or an isolated or stand-alone Joule-Thompson skid is not a natural gas processing plant.

These requirements do not apply if it is determined that the use of a pneumatic controller affected facility with a bleed rate greater than the applicable standard is required based on functional needs, including but not limited to response time, safety and positive actuation. However, an applicable pneumatic controller must be tagged with the month and year of installation, reconstruction or modification, and identification information that allows traceability to the records for that pneumatic controller.

The Ventura County APCD does not require permits for the installation and operation of pneumatic controllers and other components such as valves and flanges (Rule 23.J.9). Therefore, this condition authorizes the work necessary to comply with these pneumatic controller requirements provided that the permittee comply with all the requirements of Section 60.5390a, including the required notification, recordkeeping and reporting requirements.

5. Pneumatic pumps subject to this NSPS shall comply with Section 60.5393a. For natural gas processing plants, each pneumatic pump affected facility is a single natural gas-driven diaphragm pump. For well sites, each pneumatic pump affected facility is a single natural gas-driven diaphragm pump. A single natural gas-driven diaphragm pump that is in operation less than 90 days per calendar year is not an affected facility under this subpart provided the owner/operator keeps records of the days of operation each calendar year and submits such records to the EPA Administrator (or delegated enforcement authority) upon request.

This NSPS requires each pneumatic pump affected facility at a natural gas processing plant to have a natural gas bleed rate of zero standard cubic feet per hour. A pneumatic pump affected facility located at a well site must reduce natural gas emissions by 95.0 percent, except as provided in paragraphs (b)(3) and (4) of this section for a well site at a greenfield site, and except as provided in paragraphs (b)(3), (4) and (5) of this section for a well site not located at a greenfield site. Greenfield site is defined as a site, other than a natural gas processing plant, which is entirely new construction. Natural gas processing plants are not considered to be greenfield sites, even if they are entirely new construction.

The Ventura County APCD does not require permits for the installation and operation of pneumatic pumps and other components such as valves and flanges (Rule 23.J.9). Therefore, this condition authorizes the work necessary to comply with these pneumatic pump requirements provided that the permittee comply with all the requirements of Section 60.5393a, including the required notification, recordkeeping and reporting requirements.

6. Storage vessels subject to this NSPS shall comply with Section 60.5395a. A storage vessel is defined as a tank or other vessel that contains an accumulation of crude oil, condensate, intermediate hydrocarbon liquids, or produced water, and that is constructed primarily of non-earthen materials (such as wood, concrete, steel, fiberglass, or plastic) which provide structural support. A well completion vessel that receives recovered liquids from a well after startup of production following flowback for a period which exceeds 60 days is considered a storage vessel under this NSPS. Note that pressure vessels designed to operate in excess of 204.9 kilopascals (29.7 psi) and without emissions to the atmosphere are not considered to be storage vessels. Also, process vessels such as surge control vessels, bottoms receivers, and knockout vessels are not considered to be storage vessels.

The NSPS requires that individual storage vessels with VOC emissions equal to or greater than 4 tons per year achieve at least 95.0 percent reduction in VOC emissions. These requirements do not apply to storage vessels subject to and controlled in accordance with the requirements for storage vessels in 40 CFR Part 60, Subpart Kb, and 40 CFR Part 63, Subparts G, CC, HH, or WW.

The Ventura County APCD does require permits for the installation and operation of storage vessels such as crude oil storage tanks, wash tanks, and produced water storage tanks. Pressure vessels without routine emissions to the atmosphere are not required to be listed on the permit. In addition, these tanks must comply with the vapor recovery requirements of Rule 71.1, "Crude Oil Production and Separation", which in most cases is more stringent than this NSPS.

7. Fugitive emissions from well sites and compressor stations, except compressors located at a well site or compressors located at an onshore natural gas processing plant, subject to

this NSPS shall comply with Section 60.5397a.

The NSPS requires a leak detection and repair program for fugitive emissions components such as valves, connectors, pressure relief devices, open-ended lines, flanges, certain covers and closed vent systems, thief hatches or other openings on a controlled storage vessel (not subject to Section 60.5395a), compressors, instruments, and meters. An emissions monitoring plan is required and emission monitoring surveys are required at least semiannually for well sites and a least quarterly for compressor stations. "Difficult-to-monitor" components must be monitored at least once per calendar year and "unsafe-to-monitor" components must be monitored on a schedule, as included in the monitoring plan.

Fugitive emissions are defined as: a) any visible emission from a fugitive emissions component observed using optical gas imaging, or b) an instrument reading 500 ppm or greater using EPA Method 21.

Each identified source of fugitive emissions shall be repaired or replaced as soon as practicable, but no later than 30 calendar days after the detection of the fugitive emissions, except as provided for specified repairs and replacements in the NSPS.

The Ventura County APCD does not require permits for the installation and operation of components subject to the fugitive emissions requirements of this NSPS. Therefore, this condition authorizes any work necessary to comply with these leak detection and repair requirements provided that the permittee comply with all the requirements of Section 60.5397a, including the monitoring, repair, replacement, recordkeeping and reporting requirements.

8. All process units, except compressors, located at an onshore natural gas processing plant subject to this NSPS shall comply with Section 60.5400a. A process unit means components assembled for the extraction of natural gas liquids from field gas, the fractionation of the liquids into natural gas products or other operations associated with the processing of natural gas products.

The NSPS requires a leak detection and repair program for components such as pressure relief devices, pumps and valves that reflects the procedures and leak thresholds established in 40 CFR Part 60, Subpart VVa, the NSPS for Equipment Leaks of VOC in the Synthetic Organic Chemicals Manufacturing Industry (that is, this NSPS OOOO references out to NSPS VVa). For specified components, a leak is defined as 500 ppm or greater as measured by EPA Method 21, and a first attempt at a repair must be made no later than 5 calendar days after a leak is detected. The leak must be repaired as soon as practicable, but no later than 15 days after detection.

9. Sweetening units at onshore natural gas processing plants subject to this NSPS shall

comply with Section 60.5405a. A sweetening unit is defined as a process device that removes hydrogen sulfide and / or carbon dioxide from the sour natural gas stream. To qualify as a sweetening unit, there must be sulfur recovery technology with a liquid sulfur accumulation rate. These requirements do not apply to sweetening units located on offshore oil platforms in Ventura County. The requirements also do not apply to devices that remove hydrogen sulfide or carbon dioxide that use replaceable media or units that use membrane separation technology.

The NSPS requires that the sweetening unit achieve a minimum SO₂ reduction efficiency that varies from 74.0% to 99.9% depending on the hydrogen sulfide content of the acid gas and the sulfur feed rate.

The Ventura County APCD does require an Authority to Construct for the installation of a sweetening unit at both onshore natural gas plants and offshore natural gas plants. Any sweetening unit at this facility subject to this NSPS will be specifically addressed elsewhere in this permit, as applicable.

M:\TITLEV\Attachments updated\CFR600000a.docx

12. MISCELLANEOUS FEDERAL PROGRAM CONDITIONS

This section contains miscellaneous federal program conditions that are not emission unit-specific or short-term. These federal requirements are broadly applicable requirements that apply and are enforced in the same manner for all subject emissions units or short-term activities. Permit conditions associated with these miscellaneous federal program requirements are listed in individual attachments. The attachment is identified with the label "Attachment 40CFR(Part No.) __" in the lower left corner of each attachment.

**Ventura County Air Pollution Control District
40 CFR Part 68 Applicable Requirements
Accidental Release Prevention and Risk Management Plans**

**40 CFR Part 68, "List of Regulated Substances and Thresholds for Accidental Release Prevention"
Federally-Enforceable**

Applicability:

This attachment applies to regulated substances that are contained in a process at this facility and that exceed the threshold quantity, as presented in 40 CFR Part 68.130. This regulation addresses the requirements of section 112(r) of the federal Clean Air Act as amended. Specifically, this attachment applies to a facility that has stated that a federal Risk Management Plan pursuant to section 112(r) is currently not required, but where flexibility is desired to preclude a permit reopening should 40 CFR Part 68 become an applicable requirement.

Conditions:

1. Should the stationary source, as defined in 40 CFR Part 68.3, become subject to Part 68, then the owner or operator shall submit a risk management plan (RMP) by the date specified in Part 68.10 and shall certify compliance with the requirements of Part 68 as part of the annual compliance certification as required by 40 CFR Part 70.

M:\TITLEV\Attachments updated\CFR68.docx

**Ventura County Air Pollution Control District
40 CFR Part 82 Applicable Requirements
Protection of Stratospheric Ozone**

**40 CFR Part 82, "Protection of Stratospheric Ozone"
40 CFR Part 82, Subpart B, "Servicing of Motor Vehicle Air Conditioners"
40 CFR Part 82, Subpart F, "Recycling and Emissions Reduction"
Federally Enforceable (last revised 11/18/16)**

Applicability:

This attachment applies to activities conducted at this facility that involve producing, importing, exporting, or consuming of the specified controlled substances described under 40 CFR Part 82.4. Specifically, this attachment includes the requirements of 40 CFR Part 82, Subpart B, "Servicing of Motor Vehicle Air Conditioners," and 40 CFR Part 82, Subpart F, "Recycling and Emissions Reduction."

As stated in 40 CFR Part 82.30, 40 CFR Part 82, Subpart B applies to any person performing service on a motor vehicle for consideration when this service involves the refrigerant in the motor vehicle air conditioner.

As stated in 40 CFR Part 82.150, 40 CFR Part 82, Subpart F applies to any person maintaining, servicing, or repairing appliances containing class I, class II, or non-exempt substitute refrigerants. This subpart also applies to persons disposing of such appliances (including small appliances and motor vehicle air conditioners), refrigerant reclaimers, technician certifying programs, appliance owners and operators, manufacturers of appliances, manufacturers of recovery and/or recycling equipment, approved recovery and/or recycling equipment testing organizations, and persons buying, selling, or offering to sell class I, class II, or non-exempt substitute refrigerants.

As defined in 40 CFR 82.152, *appliance* means any device which contains and uses a class I or class II substance or substitute as a refrigerant and which is used for household or commercial purposes, including any air conditioner, motor vehicle air conditioner, refrigerator, chiller, or freezer. For a system with multiple circuits, each independent circuit is considered a separate appliance. *Refrigerant* means, for purposes of this subpart, any substance, including blends and mixtures, consisting in part or whole of a class I or class II ozone-depleting substance or substitute that is used for heat transfer purposes and provides a cooling effect.

Conditions:

1. If the permittee performs a service on motor (fleet) vehicles when this service involves ozone-depleting substance refrigerant (or regulated substitute substance) in the motor vehicle air conditioner (MVAC), the permittee is subject to all the applicable

requirements as specified in 40 CFR Part 82, Subpart B, "Servicing of Motor Vehicle Air Conditioners."

The term "motor vehicle" as used in Subpart B does not include a vehicle in which final assembly of the vehicle has not been completed. The term "MVAC" as used in Subpart B does not include the air-tight sealed refrigeration system used as refrigerated cargo, or system used on passenger buses using HCFC-22 refrigerant.

2. If the permittee performs maintenance on, or services, repairs, or disposes of appliances, the permittee is subject to all of the applicable requirements as specified in 40 CFR Part 82, Subpart F, "Recycling and Emissions Reduction."

NASA Flew Gas Detectors Above California, Found 'Super Emitters'

By [Lynn Doan](#)

Updated on November 7, 2019, 2:01 AM PST

- ▶ A handful of sites account for most of California's methane
- ▶ Researchers published their survey findings in a Nature report

A methane plume captured at an oil field in California. *Source: California Air Resources Board*

Over the course of three years, [NASA](#) flew a plane carrying gas-imaging equipment above California and made a discovery that surprised even the state's own environmental agencies: A handful of operations are responsible for the vast majority of methane emissions.

In a report published in Nature on Wednesday, scientists estimated that 10% of the places releasing methane -- including landfills, natural gas facilities and dairy farms -- are responsible for more than half of the state's total emissions. And a fraction of the 272,000 sources surveyed - just 0.2% -- account for as much as 46%.

The report doesn't identify these "super emitters," but notes that landfills give off more methane than any other source in the state. NASA's equipment found that a subset of these landfills were the largest emitters in California and exhibited "persistent anomalous activity."

The study marks the first time anyone has ever carried out a systematic survey across California of methane, a greenhouse gas that's 25 times more potent than carbon dioxide in trapping heat and contributing to global warming. The release of methane has been a continual challenge for California, which has some of the most aggressive goals in the nation for curbing emissions and slowing the impacts of climate change.

NASA's aircraft made dozens of flights across 10,000 square miles from 2016 through 2018. Landfills accounted for 41% of the source emissions it identified, manure management 26% and oil and gas operations 26%.

Researchers cautioned that the survey wasn't foolproof. It was, after all, their first attempt at estimating emissions from individual sources on such a large scale over multiple years. Some of the emissions detected were intermittent, some were too small to measure and others were affected by winds.

The results, however, are already effecting change. The survey revealed four incidents of leaking natural gas distribution lines and one leaking liquefied natural gas storage tank, which operators confirmed and repaired.

NEWS | November 6, 2019

A Third of California Methane Traced to a Few Super-Emitters

By Esprit Smith,
NASA's Earth Science News Team

Views from NASA's [Methane Source Finder](#), a tool that provides methane data for the state of California. The data are derived from airborne remote-sensing, surface-monitoring networks and satellites and are presented on an interactive map alongside infrastructure information. Credit: NASA/JPL-Caltech

[Larger view](#)

NASA scientists are helping California create a detailed, statewide inventory of methane point sources — highly concentrated methane releases from single sources — using a specialized airborne sensor. The new data, published this week in the journal *Nature*, can be used to target actions to reduce emissions of this potent greenhouse gas.

Like carbon dioxide, methane traps heat in the atmosphere, but it does so more efficiently and for a shorter period of time. Scientists estimate that most methane emissions in California are driven by industrial facilities, such as oil and gas fields, large dairies and landfills. To help reduce methane's impact on climate, the state has made cutting human-caused emissions a priority. But in order to cut these hard-to-detect emissions, they have to be measured and the sources identified.

NASA, through partnerships with the California Air Resources Board (CARB) and the California Energy Commission, set out to do just that. Over a two-year period, a research team at NASA's Jet Propulsion Laboratory in Pasadena, California, flew a plane equipped with the [Airborne Visible InfraRed](#)

[Imaging Spectrometer - Next Generation \(AVIRIS-](#)

[NG](#)) instrument over nearly 300,000 facilities and infrastructure components in those sectors. The instrument can detect plumes of methane in great detail. Each pixel covers an area of about 10 feet (3 meters) across, which allows scientists to see even small plumes that often go undetected.

The team identified more than 550 individual point sources emitting plumes of highly concentrated methane. Ten percent of these sources, considered super-emitters, contributed the majority of the emissions detected. The team estimates that statewide, super-emitters are responsible for about a third of California's total methane budget.

Emissions data like this can help facility operators identify and correct problems — and in turn, bring California closer to its emissions goals. For example, of the 270 surveyed landfills, only 30 were observed to emit large plumes of methane. However, those 30 were responsible for 40 percent of the total point-source emissions detected during the survey. This type of data could help these facilities to identify possible leaks or malfunctions in their gas-capture systems.

"These findings illustrate the importance of monitoring point sources across multiple sectors [of the economy] and broad regions, both for improved understanding of methane budgets and to support emission mitigation efforts," said the lead scientist on the study, Riley Duren, who conducted the work for NASA's Jet Propulsion Laboratory.

Initial results have been shared with facility operators in California to make them aware of the need to improve their methane-leak detection processes and to institute better controls on methane emissions. Results will also be used to help state and local agencies and businesses prioritize investments in methane-emission mitigation.

Although the survey provides a detailed map of methane emissions for the areas observed in the state, researchers caution that this was the first attempt to estimate emissions for individual methane sources from a large population distributed across such an extensive area over multiple years.

Additionally, this survey was designed to detect highly concentrated releases of methane from a single component or piece of industrial equipment, such as an oil well. The survey excluded non-point sources, such as small natural gas

leaks from millions of homes, because even though they may have a collective impact on atmospheric methane levels, their individual emissions are below the detection levels of this method.

The survey builds on a decade of cooperation between NASA, CARB and the California Energy Commission to support the state's ambitious climate change mitigation program, specifically on the study of air pollution impacts from the oil and gas sector.

"This new remote-sensing technology addresses the continuing need for detailed, high-quality data about methane," said California Air Resources Board Chair Mary D. Nichols. "It will help us and the Energy Commission develop the best strategies for capturing this highly potent greenhouse gas."

The final report of the California Methane Survey will be available in the fall.

The map and data from this survey can be viewed here:

Figure 8.29 | Development of AGWP-CO₂, AGWP-CH₄ and GWP-CH₄ with time horizon. The yellow and blue curves show how the AGWPs changes with increasing time horizon. Because of the integrative nature the AGWP for CH₄ (yellow curve) reaches a constant level after about five decades. The AGWP for CO₂ continues to increase for centuries. Thus the ratio which is the GWP (black curve) falls with increasing time horizon.

on the relative weight assigned to effects at different times. Other important choices include the background atmosphere on which the GWP calculations are superimposed, and the way indirect effects and feedbacks are included (see Section 8.7.1.4).

For some gases the variation in GWP with time horizon mainly reflects properties of the reference gas, not the gas for which the GWP is calculated. The GWP for NTCFs decreases with increasing time horizon, as GWP is defined with the integrated RF of CO₂ in the denominator. As shown in Figure 8.29, after about five decades the development in the GWP for CH₄ is almost entirely determined by CO₂. However, for long-lived gases (e.g., SF₆) the development in GWP is controlled by both the increasing integrals of RF from the long-lived gas and CO₂.

8.7.1.3 The Global Temperature change Potential Concept

Compared to the GWP, the Global Temperature change Potential (GTP; Shine et al., 2005a) goes one step further down the cause–effect chain (Figure 8.27) and is defined as the *change in global mean surface temperature at a chosen point in time* in response to an emission pulse—relative to that of CO₂. Whereas GWP is integrated in time (Figure 8.28a), GTP is an end-point metric that is based on temperature change for a selected year, t , (see Figure 8.28b with formula). Like for the GWP, the impact from CO₂ is normally used as reference, hence, for a component i , $GTP(t)_i = AGTP(t)_i / AGTP(t)_{CO_2} = \Delta T(t)_i / \Delta T(t)_{CO_2}$, where AGTP is the absolute GTP giving temperature change per unit emission (see Supplementary Material Section 8.SM.11 for equations and parameter values). Shine et al. (2005a) presented the GTP for both pulse and sustained emission changes based on an energy balance model as well as analytical equations. A modification was later introduced (Shine et al., 2007) in which the time horizon is determined by the proximity to a target year as calculated by using scenarios and climate models (see Section 8.7.1.5).

Like GWP, the GTP values can be used for weighting the emissions to obtain ‘CO₂ equivalents’ (see Section 8.7.1.1). This gives the

temperature effects of emissions relative to that of CO₂ for the chosen time horizon. As for GWP, the choice of time horizon has a strong effect on the metric values and the calculated contributions to warming.

In addition, the AGTP can be used to calculate the global mean temperature change due to any given emission scenario (assuming linearity) using a convolution of the emission scenarios and AGTP _{i} :

$$\Delta \bar{T}(t) = \sum_{i,j} \int_{s=0}^t \bar{A}_i(s) \bar{A}_j(t-s) \Delta E_{ij}(s) ds \quad (8.1)$$

where i is component, t is time, and s is time of emission (Berntsen and Fuglestvedt, 2008; Peters et al., 2011b; Shindell et al., 2011).

By accounting for the climate sensitivity and the exchange of heat between the atmosphere and the ocean, the GTP includes physical processes that the GWP does not. The GTP accounts for the slow response of the (deep) ocean, thereby prolonging the response to emissions beyond what is controlled by the decay time of the atmospheric concentration. Thus the GTP includes both the atmospheric adjustment time scale of the component considered and the response time scale of the climate system.

The GWP and GTP are fundamentally different by construction and different numerical values can be expected. In particular, the GWPs for NTCFs, over the same time frames, are higher than GTPs due to the integrative nature of the metric. The GTP values can be significantly affected by assumptions about the climate sensitivity and heat uptake by the ocean. Thus, the relative uncertainty ranges are wider for the GTP compared to GWP (see Section 8.7.1.4). The additional uncertainty is a typical trade-off when moving along the cause–effect chain to an effect of greater societal relevance (Figure 8.27). The formulation of the ocean response in the GTP has a substantial effect on the values; thus its characterization also represents a trade-off between simplicity and accuracy. As for GWP, the GTP is also influenced by the background atmosphere, and the way indirect effects and feedbacks are included (see Section 8.7.1.4).

8.7.1.4 Uncertainties and Limitations related to Global Warming Potential and Global Temperature change Potential

The uncertainty in the numerator of GWP; that is, the AGWP _{i} (see formula in Figure 8.28a) is determined by uncertainties in lifetimes (or perturbation lifetimes) and radiative efficiency. Inclusion of indirect effects increases uncertainties (see below). For the reference gas CO₂, the uncertainty is dominated by uncertainties in the *impulse response function* (IRF) that describes the development in atmospheric concentration that follows from an emission pulse (Joos et al., 2013); see Box 6.2 and Supplementary Material Section 8.SM.12. The IRF is sensitive to model representation of the carbon cycle, pulse size and background CO₂ concentrations and climate.

Based on a multi-model study, Joos et al. (2013) estimate uncertainty ranges for the time-integrated IRF for CO₂ to be ±15% and ±25% (5 to 95% uncertainty range) for 20- and 100-year time horizons, respectively. Assuming quadratic error propagation, and ±10% uncertainty in radiative efficiency, the uncertainty ranges in AGWP for CO₂ were estimated to be ±18% and ±26% for 20 and 100 years. These

uncertainties affect all metrics that use CO₂ as reference. Reisinger et al. (2010) and Joos et al. (2013) show that these uncertainties increase with time horizon.

The same factors contribute to uncertainties in the GTP, with an additional contribution from the parameters describing the ocean heat uptake and climate sensitivity. In the first presentation of the GTP, Shine et al. (2005a) used one time constant for the climate response in their analytical expression. Improved approaches were used by Boucher and Reddy (2008), Collins et al. (2010) and Berntsen and Fuglestedt (2008) that include more explicit representations of the deep ocean that increased the long-term response to a pulse forcing. Over the range of climate sensitivities from AR4, GTP₅₀ for BC was found to vary by a factor of 2, the CH₄ GTP₅₀ varied by about 50%, while for N₂O essentially no dependence was found (Fuglestedt et al., 2010). AGTPs for CO₂ were also calculated in the multi-model study by Joos et al. (2013). They found uncertainty ranges in AGTP that are much larger than for AGWP; ±45% and ±90% for 20 and 100 years (5 to 95% uncertainty range). These uncertainty ranges also reflect the signal-to-noise ratio, and not only uncertainty in the physical mechanisms.

There are studies combining uncertainties in various input parameters. Reisinger et al. (2011) estimated the uncertainty in the GWP for CH₄ and found an uncertainty of −30 to +40% for the GWP₁₀₀ and −50 to +75% for GTP₁₀₀ of CH₄ (for 5 to 95% of the range). Boucher (2012) performed a Monte Carlo analysis with uncertainties in perturbation lifetime and radiative efficiency, and for GWP₁₀₀ for CH₄ (assuming a constant background atmosphere) he found ±20%, and −40 to +65 for GTP₁₀₀ (for 5 to 95% uncertainty range).

Here we estimate uncertainties in GWP values based on the uncertainties given for radiative efficiencies (Section 8.3.1), perturbation lifetimes, indirect effects and in the AGWP for the reference gas CO₂ (see Supplementary Material Section 8.SM.12). For CH₄ GWP we estimate an uncertainty of ±30% and ±40% for 20- and 100-year time horizons, respectively (for 5 to 95% uncertainty range). The uncertainty is dominated by AGWP for CO₂ and indirect effects. For gases with lifetimes of a century or more the uncertainties are of the order of ±20% and ±30% for 20- and 100-year horizons. The uncertainty in GWPs for gases with lifetimes of a few decades is estimated to be of the order of ±25% and ±35% for 20 and 100 years. For shorter-lived gases, the uncertainties in GWPs will be larger (see Supplementary Material Section 8.SM.12 for a discussion of contributions to the total uncertainty.) For GTP, few uncertainty estimates are available in the literature. Based on the results from Joos et al. (2013), Reisinger et al. (2010) and Boucher (2012) we assess the uncertainty to be of the order of ±75% for the CH₄ GTP₁₀₀.

The metric values are also strongly dependent on which processes are included in the definition of a metric. Ideally all indirect effects (Sections 8.2 and 8.3) should be taken into account in the calculation of metrics. The indirect effects of CH₄ on its own lifetime, tropospheric ozone and stratospheric water have been traditionally included in its GWP. Boucher et al. (2009) have quantified an indirect effect on CO₂ when fossil fuel CH₄ is oxidized in the atmosphere. Shindell et al. (2009) estimated the impact of reactive species emissions on both gaseous and aerosol forcing species and found that ozone precursors,

including CH₄, had an additional substantial climate effect because they increased or decreased the rate of oxidation of SO₂ to sulphate aerosol. Studies with different sulphur cycle formulations have found lower sensitivity (Collins et al., 2010; Fry et al., 2012). Collins et al. (2010) postulated an additional component to their GWPs and GTPs for ozone precursors due to the decreased productivity of plants under higher levels of surface ozone. This was estimated to have the same magnitude as the ozone and CH₄ effects. This effect, however, has so far only been examined with one model. In a complex and interconnected system, feedbacks can become increasingly complex, and uncertainty of the magnitude and even direction of feedback increases the further one departs from the primary perturbation, resulting in a trade-off between completeness and robustness, and hence utility for decision-making.

Gillett and Matthews (2010) included climate–carbon feedbacks in calculations of GWP for CH₄ and N₂O and found that this increased the values by about 20% for 100 years. For GTP of CH₄ they found an increase of ~80%. They used numerical models for their studies and suggest that climate–carbon feedbacks should be considered and parameterized when used in simple models to derive metrics. Collins et al. (2013) parameterize the climate-carbon feedback based on Friedlingstein et al. (2006) and Arora et al. (2013) and find that this more than doubles the GTP₁₀₀ for CH₄. Enhancement of the GTP for CH₄ due to carbon–climate feedbacks may also explain the higher GTP values found by Reisinger et al. (2010).

The inclusion of indirect effects and feedbacks in metric values has been inconsistent in the IPCC reports. In SAR and TAR, a carbon model without a coupling to a climate model was used for calculation of IRF for CO₂ (Joos et al., 1996), while in AR4 climate-carbon feedbacks were included for the CO₂ IRF (Plattner et al., 2008). For the time horizons 20 and 100 years, the AGWP_{CO2} calculated with the Bern3D-LPJ model is, depending on the pulse size, 4 to 5% and 13 to 15% lower, respectively, when carbon cycle–climate feedbacks are not included (Joos et al., 2013). While the AGWP for the reference gas CO₂ included climate–carbon feedbacks, this is not the case for the non-CO₂ gas in the numerator of GWP, as recognized by Gillett and Matthews (2010), Joos et al. (2013), Collins et al. (2013) and Sarofim (2012). This means that the GWPs presented in AR4 may underestimate the relative impacts of non-CO₂ gases. The different inclusions of feedbacks partially represent the current state of knowledge, but also reflect inconsistent and ambiguous definitions. In calculations of AGWP for CO₂ in AR5 we use the IRF for CO₂ from Joos et al. (2013) which includes climate–carbon feedbacks. Metric values in AR5 are presented both with and without including climate–carbon feedbacks for non-CO₂ gases. This feedback is based on the carbon-cycle response in a similar set of models (Arora et al., 2013) as used for the reference gas (Collins et al., 2013).

The effect of including this feedback for the non-reference gas increases with time horizon due to the long-lived nature of the initiated CO₂ perturbation (Table 8.7). The relative importance also increases with decreasing lifetime of the component, and is larger for GTP than GWP due to the integrative nature of GWP. We calculate an increase in the CH₄ GWP₁₀₀ of 20%. For GTP₁₀₀, however, the changes are much larger; of the order of 160%. For the shorter time horizons (e.g., 20 years) the effect of including this feedback is small (<5%) for both GWP

Table 8.7 | GWP and GTP with and without inclusion of climate–carbon feedbacks (cc fb) in response to emissions of the indicated non-CO₂ gases (climate-carbon feedbacks in response to the reference gas CO₂ are always included).

Notes:

Uncertainties related to the climate–carbon feedback are large, comparable in magnitude to the strength of the feedback for a single gas.

^a Perturbation lifetime is used in the calculation of metrics.

^b These values do not include CO₂ from methane oxidation. Values for fossil methane are higher by 1 and 2 for the 20 and 100 year metrics, respectively (Table 8.A.1).

and GTP. For the more long-lived gases the GWP₁₀₀ values increase by 10 to 12%, while for GTP₁₀₀ the increase is 20 to 30%. Table 8.A.1 gives metric values including the climate–carbon feedback for CO₂ only, while Supplementary Material Table 8.SM.16 gives values for all halocarbons that include the climate–carbon feedback. Though uncertainties in the carbon cycle are substantial, it is *likely* that including the climate–carbon feedback for non-CO₂ gases as well as for CO₂ provides a better estimate of the metric value than including it only for CO₂.

Emission metrics can be estimated based on a constant or variable background climate and this influences both the adjustment times and the concentration–forcing–temperature relationships. Thus, all metric values will need updating due to changing atmospheric conditions as well as improved input data. In AR5 we define the metric values with respect to a constant present-day condition of concentrations and climate. However, under non-constant background, Joos et al. (2013) found decreasing CO₂ AGWP₁₀₀ for increasing background levels (up to 23% for RCP8.5). This means that GWP for all non-CO₂ gases (except CH₄ and N₂O) would increase by roughly the same magnitude. Reisinger et al. (2011) found a reduction in AGWP for CO₂ of 36% for RCP8.5 from 2000 to 2100 and that the CH₄ radiative efficiency and AGWP also decrease with increasing CH₄ concentration. Accounting for both effects, the GWP₁₀₀ for CH₄ would increase by 10 to 20% under low and mid-range RCPs by 2100, but would decrease by up to 10% by mid-century under the highest RCP. While these studies have focused on the background levels of GHGs, the same issues apply for temperature. Olivé et al. (2012) find different temperature IRFs depending on the background climate (and experimental set up).

User related choices (see Box 8.4) such as the time horizon can greatly affect the numerical values obtained for CO₂ equivalents. For a change in time horizon from 20 to 100 years, the GWP for CH₄ decreases by a factor of approximately 3 and its GTP by more than a factor of 10. Short-lived species are most sensitive to this choice. Some approaches have removed the time horizon from the metrics (e.g., Boucher, 2012), but discounting is usually introduced which means that a discount rate

r (for the weighting function e^{-rt}) must be chosen instead. The choice of discount rate is also value based (see WGIII, Chapter 3).

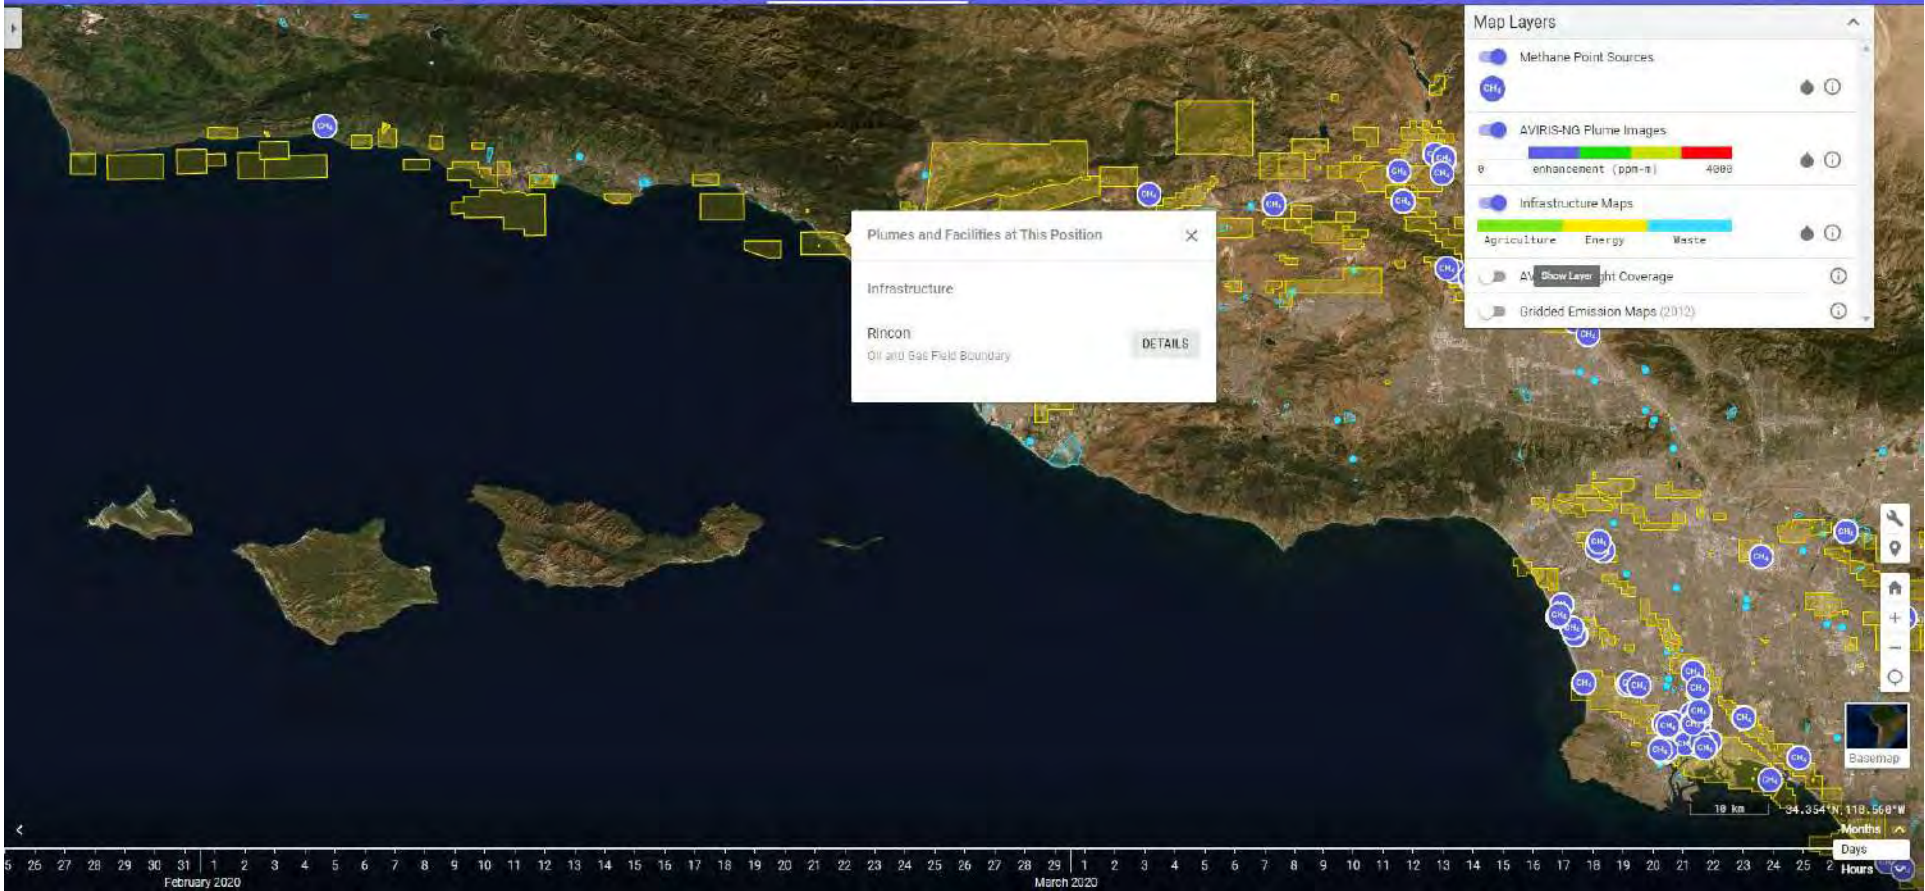

For NTCFs the metric values also depend on the location and timing of emission and whether regional or global metrics are used for these gases is also a choice for the users. Metrics are usually calculated for pulses, but some studies also give metric values that assume constant emissions over the full time horizon (e.g., Shine et al., 2005a; Jacobson, 2010). It is important to be aware of the idealized assumption about constant future emissions (or change in emissions) of the compound being considered if metrics for sustained emissions are used.

8.7.1.5 New Metric Concepts

New metric concepts have been developed both to modify physical metrics to address shortcomings as well as to replace them with metrics that account for economic dimensions of problems to which metrics are applied. Modifications to physical metrics have been proposed to better represent CO₂ emissions from bioenergy, regional patterns of response, and for peak temperature limits.

Emissions of CO₂ from the combustion of biomass for energy in national emission inventories are currently assumed to have no net RF, based on the assumption that these emissions are compensated by biomass regrowth (IPCC, 1996). However, there is a time lag between combustion and regrowth, and while the CO₂ is resident in the atmosphere it leads to an additional RF. Modifications of the GWP and GTP for bioenergy (GWP_{bio}, GTP_{bio}) have been developed (Cherubini et al., 2011; Cherubini et al., 2012). The GWP_{bio} give values generally between zero (current default for bioenergy) and one (current for fossil fuel emissions) (Cherubini et al., 2011), and negative values are possible for GTP_{bio} due to the fast time scale of atmospheric–ocean CO₂ exchange relative to the growth cycle of biomass (Cherubini et al., 2012). GWP_{bio} and GTP_{bio} have been used in only a few applications, and more research is needed to assess their robustness and applicability. Metrics for biogeophysical effects, such as albedo changes, have been proposed (Betts, 2000; Rotenberg and Yakir, 2010), but as for NTCFs regional variations

Carbon Energy Corporation

Corporate Overview

2019

IMPORTANT DISCLOSURES

Forward-Looking Statements

The slides contain certain forward-looking statements within the meaning of Section 27A of the Securities Act of 1933, as amended (the “Securities Act”), and Section 21E of the Securities Exchange Act of 1934, as amended (the “Exchange Act”). Except for historical information, statements made in the slide presentation, including those relating to the Company’s strategies, estimated and anticipated production, expenditures, infrastructure, estimated costs, number of wells to be drilled, estimated reserves, reserve potential, recoverable reserves, and financial position are forward-looking statements as defined by the Securities and Exchange Commission. These statements are based on assumptions and estimates that management believes are reasonable based on currently available information; however, management’s assumptions and the Company’s future performance are subject to a wide range of business risks and uncertainties and there is no assurance that these goals and projections can or will be met. Any number of factors could cause actual results to differ materially from those in the forward-looking statements, including, but not limited to, the volatility of oil and gas prices, the costs and results of drilling and operations, the timing of production, mechanical and other inherent risks associated with oil and gas production, weather, the availability of drilling equipment, changes in interest rates, litigation, uncertainties about reserve estimates, and environmental risk. We caution you not place undue reliance on these forward-looking statements, which speak only as of the date reflected in the slide presentation, and we undertake no obligation to publicly update or revise any forward-looking statements. Further information on risks and uncertainties is available in the Company’s filings with the Securities and Exchange Commission, which are incorporated by reference.

Actual quantities of oil and gas that may be ultimately recovered from Carbon’s interests will differ substantially from our estimates. Factors affecting ultimate recovery include the scope of Carbon’s drilling program, which will be directly affected by the availability of capital, drilling and production costs, commodity prices, availability of drilling services and equipment, drilling results, lease expirations, transportation constraints, regulatory approvals, field spacing rules, recovery of gas in place, length of horizontal laterals, actual drilling results, and geological and mechanical factors affecting recovery rates and other factors. Estimates of reserves potential may change significantly as development of our reserves plays provides additional data. Investors are urged to consider closely the disclosure in our filings with the SEC available upon request to: Corporate Secretary, Carbon Energy Corporation, 1700 Broadway, Suite 1170, Denver, Colorado 80290; tel: (720) 407-7030. You can also obtain our public filings from the SEC’s website, <http://www.sec.gov>.

Non-GAAP Measures

The slide presentation contains certain references to EBITDA and Adjusted EBITDA value, which are non-GAAP financial measures, as defined under Regulation G of the rules and regulations of the SEC.

EBITDA and Adjusted EBITDA

“EBITDA” and “Adjusted EBITDA” are non-GAAP financial measures. We define EBITDA as net income or loss before interest expense, taxes, depreciation, depletion and amortization. We define Adjusted EBITDA as EBITDA prior to accretion of asset retirement obligations, ceiling test write downs of oil and gas properties, non-cash stock-based compensation expense and the gain or loss on sold investments or properties. EBITDA and Adjusted EBITDA is consolidated including non-controlling interests and as used and defined by us, may not be comparable to similarly titled measures employed by other companies and are not measures of performance calculated in accordance with GAAP. EBITDA and Adjusted EBITDA should not be considered in isolation or as a substitute for operating income, net income or loss, cash flows provided by or used in operating, investing and financing activities, or other income or cash flow statement data prepared in accordance with GAAP. EBITDA and Adjusted EBITDA provide no information regarding a company’s capital structure, borrowings, interest costs, capital expenditures, and working capital movement or tax position. EBITDA and Adjusted EBITDA do not represent funds available for discretionary use because those funds are required for debt service, capital expenditures, working capital, income taxes, franchise taxes, exploration and development expenses, and other commitments and obligations. However, our management believes EBITDA and Adjusted EBITDA are useful to an investor in evaluating our operating performance because these measures are widely used by investors in the oil and natural gas industry to measure a company’s operating performance without regard to items excluded from the calculation of such term, which can vary substantially from company to company depending upon accounting methods and book value of assets, capital structure and the method by which assets were acquired, among other factors; and help investors to more meaningfully evaluate and compare the results of our operations from period to period by removing the effect of our capital structure from our operating structure; and are used by our management for various purposes, including as a measure of operating performance, in presentations to our board of directors, as a basis for strategic planning and forecasting and by our lenders pursuant to a covenant under our credit facility.

There are significant limitations to using EBITDA and Adjusted EBITDA as a measure of performance, including the inability to analyze the effect of certain recurring and non-recurring items that materially affect our net income or loss, the lack of comparability of results of operations of different companies and the different methods of calculating EBITDA and Adjusted EBITDA reported by different companies.

Carbon Strategy

- **Emphasize Health, Safety and Environmental best practices and compliance**
- **Acquire and develop oil and gas producing assets**
 - **Appalachian Basin**
 - **Ventura Basin**
- **Build value from acquired assets through**
 - **Lease operating expense reductions**
 - **Gathering and compression optimization**
 - **Return to production projects**
 - **Recompletions**
 - **Operational synergies**
- **Utilize science and technology to develop assets with highest rate of return on capital invested**
- **Develop assets through drilling as commodity prices warrant**
- **Maintain favorable debt metrics and financial flexibility**
- **Management team has long-term successful track record of creating value for its shareholders and partners**
- **Strong technical team with acquisition, production and drilling expertise**

Carbon Growth Strategy

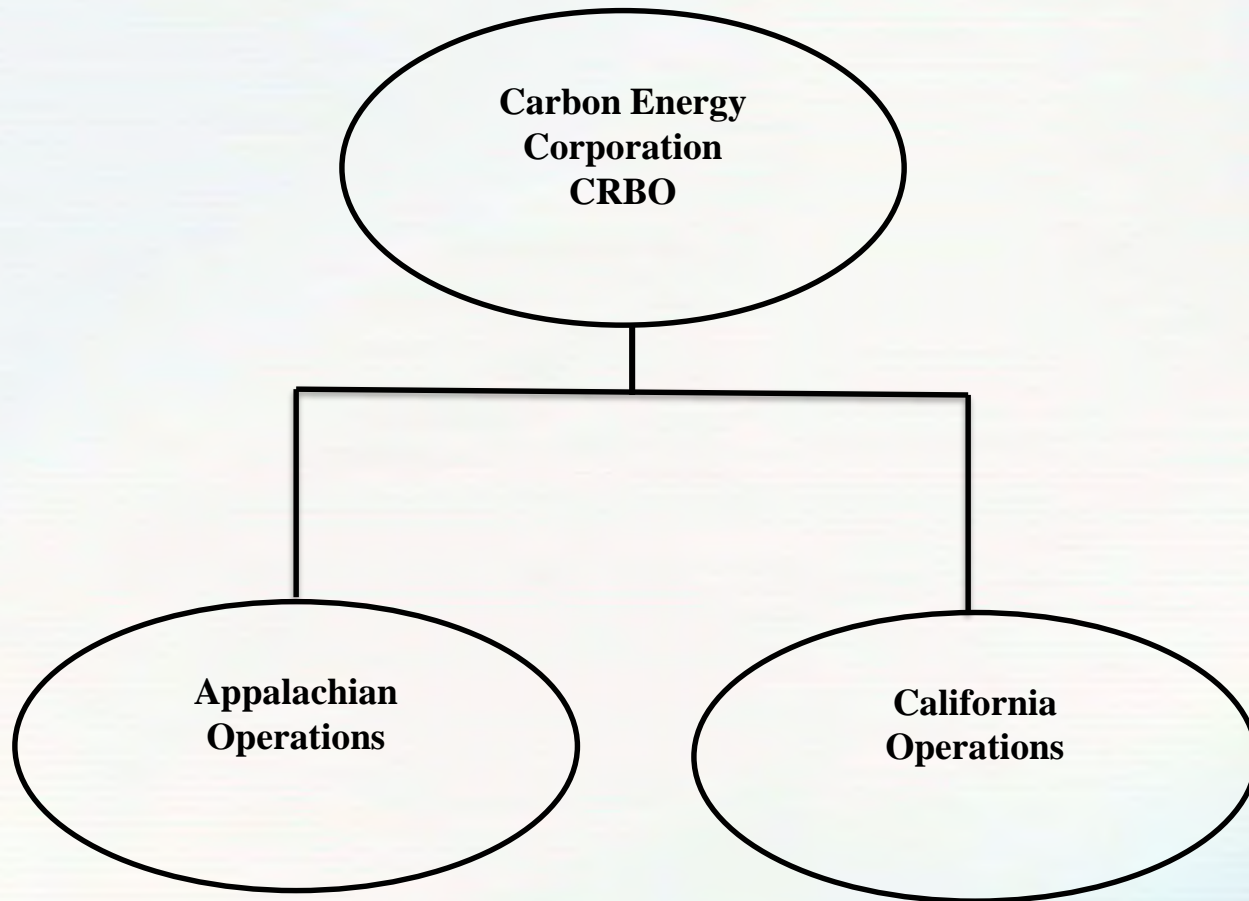

Acquire and Develop

Appalachian Basin

- Legacy producers are divesting southern Appalachia production and midstream assets.
- This creates opportunity to acquire and develop producing and midstream assets and consolidate a southern Appalachian position.
- Extensive field development opportunities exist within the company's existing properties.

Ventura Basin, California

- Legacy producers are divesting Ventura Basin production and midstream assets.
- This creates an opportunity to acquire and develop a portfolio of light oil, low operating cost producing properties.
- Extensive field development opportunities exist within the company's existing properties.

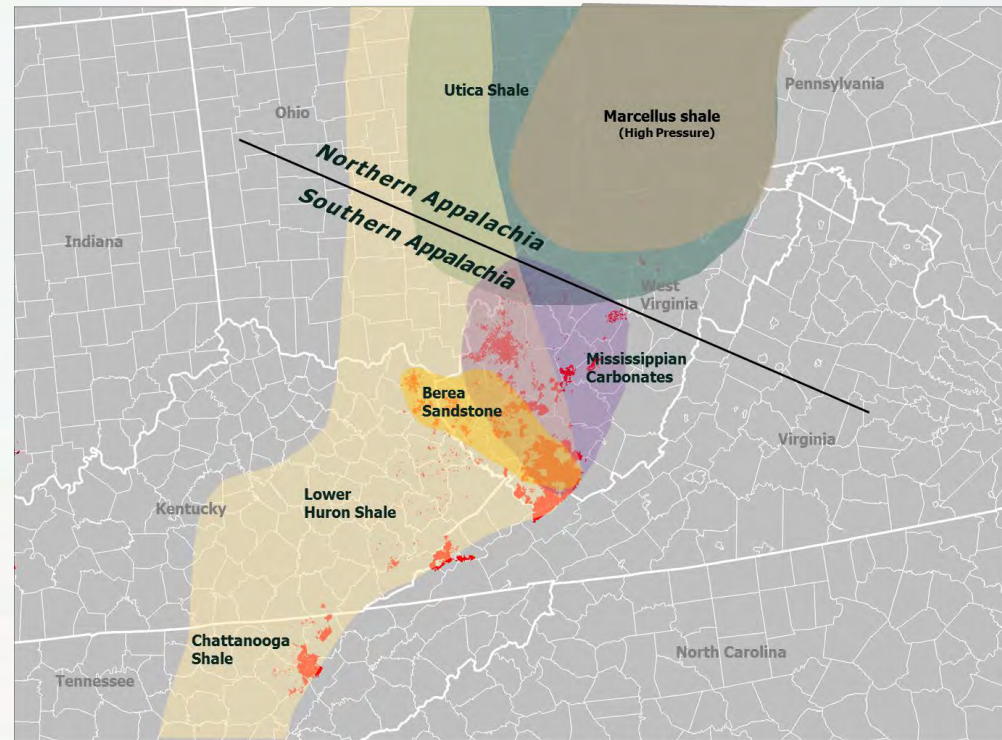

Southern Appalachian Basin Investment Strategy

Northern and Southern Appalachia are both historical producing regions.

Both have same geologic history and similar producing formations.

- ***Marcellus and Utica Shales in North***
 - ✓ Very high land, drilling and completion costs
 - ✓ Low gas price netback
 - ✓ Highly competitive
- ***Huron/Chattanooga Shale in the South***
 - ✓ Reasonable costs
 - ✓ Attractive gas price netback
 - ✓ Lack of competition

Exploration and production companies are divesting legacy production in Southern Appalachia to focus on the Marcellus and Utica Shales in the north.

This creates opportunity for Carbon to acquire and develop producing assets in the south, build on existing operations, and to consolidate Southern Appalachian position.

Carbon Appalachian Basin Assets

Carbon Appalachian Basin Operations

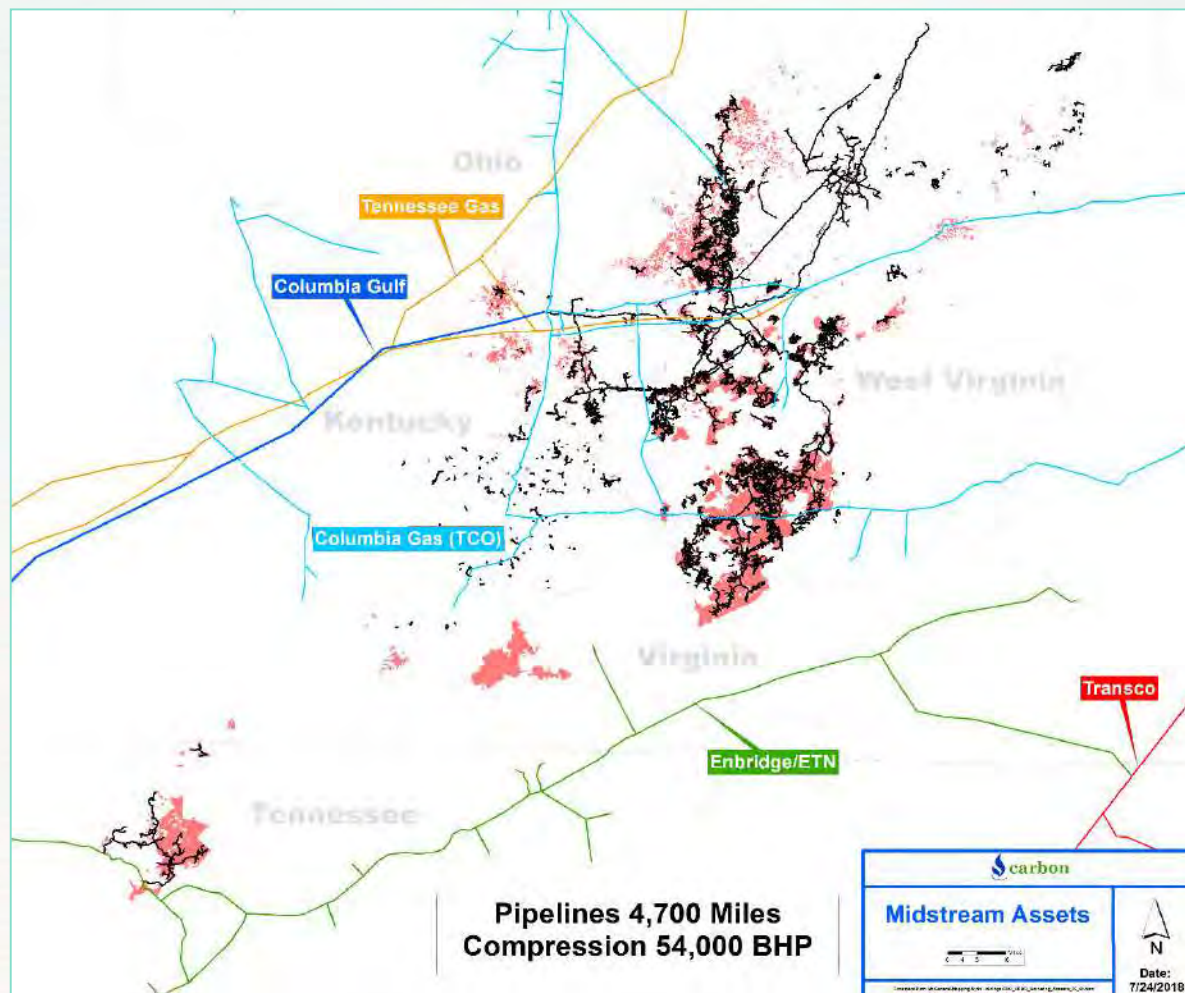

- **Approximately 60,000 mcfe net daily production, 90% operated**
- **Proved reserves of 442 bcfe**
- **Interest in approximately 8,200 wells**
- **Ownership of 4,700 miles of midstream gathering pipelines and associated compression facilities**
- **Multiple direct connect end use customers and transportation pipeline interconnects**
- **Operation of natural gas storage facilities enhances midstream operations**
- **Approximately 1,650,000 net acres of oil, gas and/or coalbed methane rights**
 - **73% Held by Production**
 - **80% of remainder expires later than 5 years**
- **Extensive Inventory of Field Development Projects**
 - **Berea Sandstone Oil**
 - **Lower Huron Shale**
 - **Chattanooga Shale**
- **Low lease operating expenses**
- **High BTU natural gas in close proximity to market, average netback price Nymex \$(0.25)/mmbtu**

Southern Appalachia | *Midstream Business Segment*

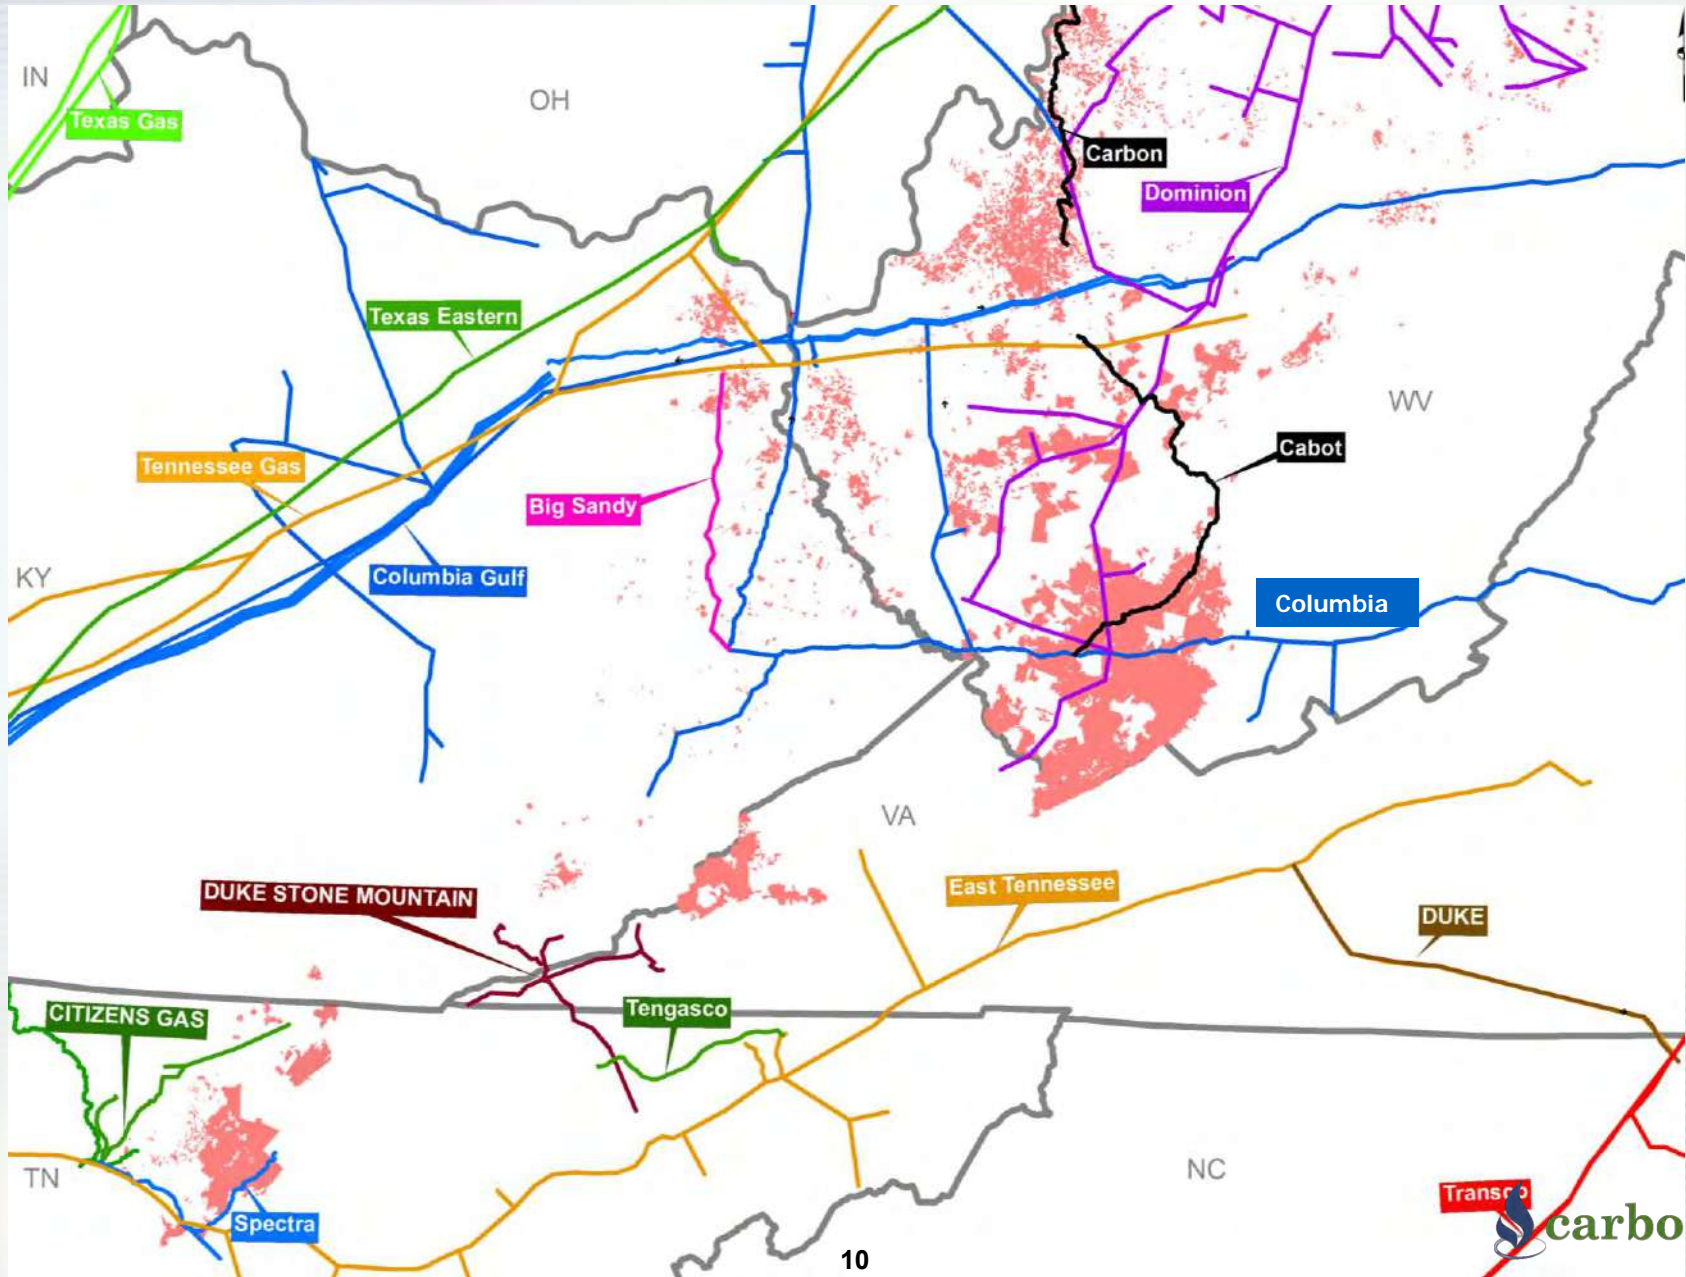

Overview

- System transports over 90 MMcf/d
- Direct on system industrial end use customers
- Carbon owned gas storage facilities provide direct end user sales flexibility and gas marketing opportunities
- Extensive gathering and compression system basin wide
 - Gas Gathering: 4,700 miles of pipe
 - Compression: 54,000 BHP
- Access to 3rd party pipelines (TCO, ETN, DTI) provide gas marketing and index arbitrage opportunities
- Firm transport agreements on main line transportation pipelines

Asset Locator Map

Transportation Pipeline Access

California Oil and Gas Basins

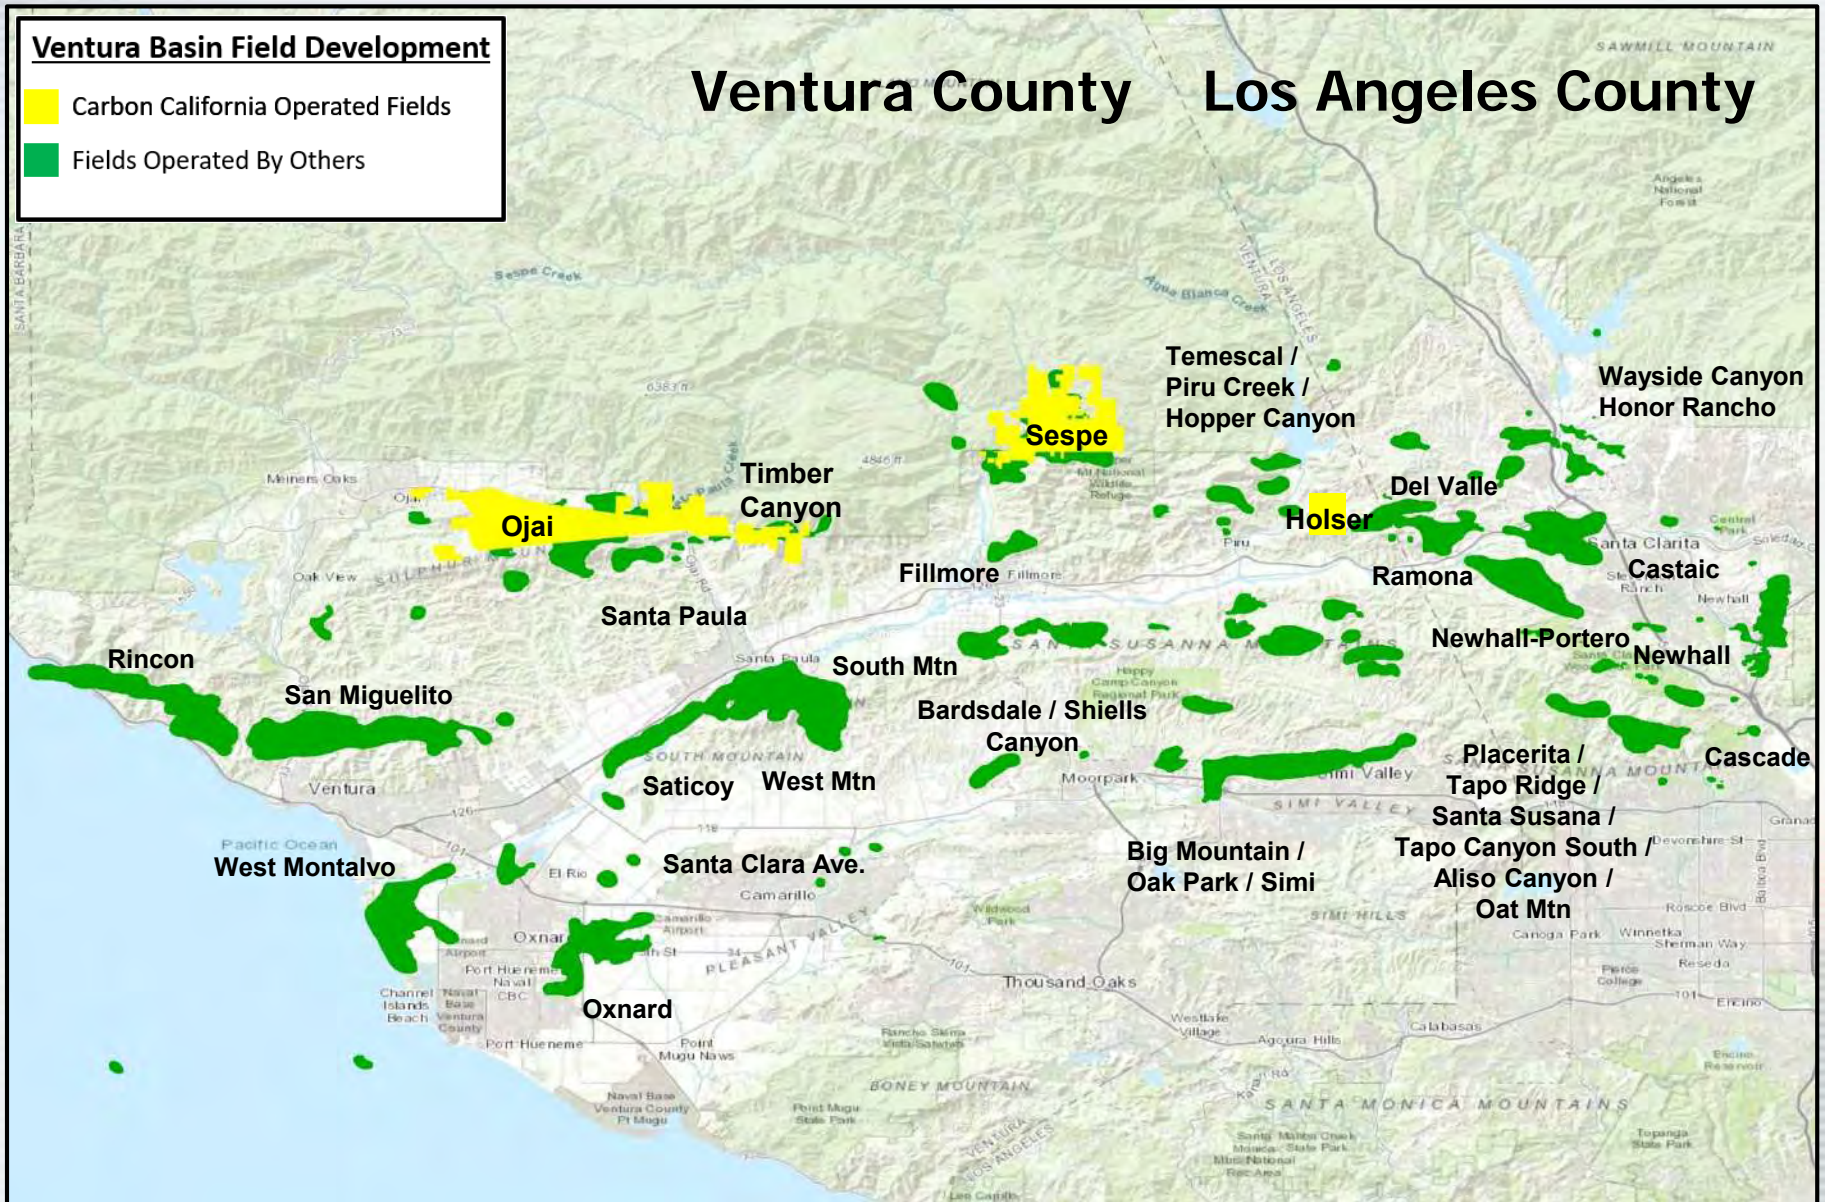

Ventura Basin

Ventura County

Los Angeles County

Ventura Basin Field Development

- Carbon California Operated Fields
- Fields Operated By Others

Ventura Basin Investment Strategy

- Carbon has identified the Ventura Basin of California as an area which presents an excellent opportunity to acquire and develop a portfolio of light oil, low operating cost producing properties
- Carbon has acquired Ojai Field, Timber Canyon Field, Holser Field and Sespe Field assets, and is currently implementing production optimization programs and field development
- Carbon will grow the asset base through low-risk exploitation and development of the properties

➤ California Acquisition Criteria

- Shallow decline, long life reserves
- Low capital maintenance requirements
- Multipay “conventional” producing formations
- No thermal / steam flood operations
- Light crude oil
- Low water cut
- Shallow depth (2,000’ to 6,500’)
- Permitted water management systems
- Favorable land and regulatory environment

Carbon Ventura Basin California

- **1,400 barrels of oil and liquids per day and 1,860 mcf of gas per day net production, 100% operated**
- **Proved reserves of 23.1 million barrels of oil equivalent (84% oil and NGL)**
- **Interest in approximately 570 wells**
- **Approximately 17,000 net acres of oil, gas rights**
 - **100% Held by Production**
 - **7,700 mineral fee acres**
- **Multiple producing horizons**
- **Low lease operating expenses**
- **Brent oil price**
- **Inventory of Return to Production, Behind Pipe Recompletion and Proved Undeveloped drilling projects**
- **Operating cost improvements through facility consolidation**

EXHIBIT 12

INTERIM VARIANCE ORDER NUMBER

Page 1

BEFORE THE HEARING BOARD
OF THE
VENTURA COUNTY AIR POLLUTION CONTROL DISTRICT
STATE OF CALIFORNIA

In the matter of the application of:

Carbon California Operating Company
270 Quail Ct, Suite B
Santa Paula, CA 93060

For a variance from:

Rule 29.C, Conditions on Permits –
Violation of Condition 3

APCD Permit to Operate No. 00939

Hearing Board Case No. 878

ORDER
GRANTING
INTERIM VARIANCE

Granted: August 26, 2019

Effective to: November 22, 2019

On August 12, 2019, PETITIONER CARBON CALIFORNIA OPERATING COMPANY (Carbon), filed with this Hearing Board petitions for Interim and Regular Variances pursuant to California Health and Safety Code Section 42350(a). The petitioner requested that the Hearing Board grant an interim variance from District Rule 29.C, Conditions on Permits – Violation of Permit to Operate (PO) No. 00939, Condition 3.

Petitioner is requesting authorization to continue operating the permitted 18.0 million British Thermal Units per hour (MMBTU/hr) Waste Gas Flare with excess emissions. A regular variance hearing will be held on or before November 22, 2019. Notice of the application and hearing is not required for interim variances.

On August 26, 2019, a hearing on the petition for variance was held. The Ventura County Air Pollution Control District (District) was represented by Mr. Keith Macias, Compliance Manager, and Ms. Michelle Wood, Supervising Air Quality Specialist. The Petitioner was represented by Mr. Scott Price, President, Carbon, Mr. Luke Faith, Area Manager, Carbon, Ms. Jane Farkas, Director of Land & Regulatory Affairs, Carbon, and Mr. Rob Alfaro, Vice President, Sespe Consulting. All persons, including the public, were given the opportunity to give testimony or make comment.

INTERIM VARIANCE ORDER NUMBER

Page 2

The Hearing Board heard testimony on the "good cause" issue set forth in Section 42351(b) of the California Health and Safety Code. Section 42351(b) states in part: "An interim variance may be granted for good causes stated in the order granting such a variance."

The Hearing Board declared the hearing closed after receiving testimony and took the matter under submission for decision. The Hearing Board made the following findings of fact.

EQUIPMENT AND LOCATION

1. Petitioner is in the business of producing and separating crude oil and natural gas. Carbon's Clark and West Leases, Timber Canyon is located in a remote area north of the City of Santa Paula, Ventura County, California.
2. The subject equipment consists of a 18.0 MMBTU/hr Waste Gas Flare, authorized by District Permit to Operate number 00939.

BACKGROUND

Natural gas is a byproduct of crude oil production. Gas may be collected from oil wells and storage tanks, compressed and sent to sales via a pipeline. When it is not possible to sell the natural gas, due to sales pipeline problems or electrical failure, the produced gas must be flared, or the entire facility must be shut down.

The emission source authorized by District PO number 00939 is one 18.0 MMBTU/hr Waste Gas Flare. The flare is used to manage produced gas attendant to oil-gas production operations. As opposed to "stacking" gas, which can impact the environment and present a safety hazard and is prohibited by District Rules. The flare provides an effective way to temporarily manage gas from operations attendant to oil-gas production, maintenance activities, and ancillary operating and processing when it cannot be sent via pipeline.

Carbon and California Resources Petroleum Corporation (CRC) are parties to a Gas Treating and Purchase Agreement dated September 19, 2002, where Carbon sends the natural gas produced to CRC for processing and sales to the Southern California Gas Company (SoCal Gas).

On June 26, 2019, CRC notified Carbon that, due to a SoCal Gas project that includes the relocation and repair to the main pipeline that CRC delivers gas to, SoCal Gas has significantly reduced the amount of gas that CRC can deliver into the existing pipeline. Due to this "force majeure" event, CRC indicated that it temporarily would not accept gas

from Carbon into the CRC pipeline system as of June 27, 2019. This limitation on Carbon's gas deliveries will continue until SoCal Gas has completed the relocation and repairs of the main pipeline or until CRC develops an alternative pipeline option. There are no current alternative sales gas lines available to Carbon. The event was unexpected and completely out of Carbon's control.

On June 27, 2019, CRC shut-in Carbon and stopped receiving natural gas from Carbon's pipelines. Since June 27, 2019, Carbon has flared its gas consistent with Carbon's allowed fuel consumption limit for the flare under District PO number 00939.

On July 2, 2019, Carbon informed the District that they believed the unexpected SoCal Gas event will eventually cause an exceedance of the permitted fuel consumption limit for the flare.

On August 12, 2019, Carbon filed an interim variance petition with the Clerk of the Board, as well as a regular variance petition. Carbon is seeking a variance because CRC's gas processing system, which is the only market for produced gas from Carbon's existing fields, is currently constrained. Carbon currently has no other feasible option than to flare the gas until the pipelines to CRC are available for processing. Carbon currently has no other alternative means to dispose of the produced gas. Additionally, there are no mitigation measures available.

Carbon intends to come into compliance by feeding natural gas back into the line to CRC as soon as CRC allows the produced gas back in. Carbon has also been in communication with CRC regarding the potential for tying into an alternative SoCal Gas sales line. CRC is currently in the process of permitting additional equipment with the District and Ventura County Planning that will enable Carbon to feed natural gas into the line to CRC in the near term and before the completion of the SoCal Gas project. CRC is working with the County of Ventura to ensure that this alternative be permitted as soon as possible. CRC notified Carbon that this alternative gas line may be available for Carbon to access as soon as October. In addition, CRC recently completed a project involving a high-pressure line that has facilitated Carbon's natural gas transmission into that line from the temporarily shut-in Sespe Field Leases and the flaring at that site associated with this unexpected event has already ceased.

RULE REQUIREMENTS AND VIOLATIONS

The operations at the facility are subject to California statutes and District Rules and Regulations. The following District Rule is applicable to this Interim Variance.

INTERIM VARIANCE ORDER NUMBER

Page 4

District Rule 29.C, Conditions on Permits - Violation of Permit Conditions, requires permit holders to comply with the conditions on their permits. Carbon's PO No. 00939, Condition 3 states in part:

“Gas consumption for the emergency flare shall not exceed 11.8 million cubic feet (MMCF) of gas per year for any planned flaring events. There is no limit for emergency use. Emergency use is defined as disposal of process gasses in the event of unavoidable process upsets.... If a process upset (emergency use) cannot be rectified in a reasonable amount of time, the use of the flare may be determined to be a planned flaring event.”

If Carbon continues to operate the oil production equipment at the Clark and West Leases, Timber Canyon, natural gas will be produced and must be controlled through flaring. Continued operation of the Clark and West Leases will exceed PO Number 00939, Condition 3 flaring limit and Carbon will be in violation of District Rule 29.C until the pipelines to CRC are available for processing.

GOOD CAUSE

The SoCal Gas line shut down and “force majeure” event was unexpected and completely out of Carbon's control. Carbon has no control of the pipeline and both CRC and SoCal Gas' schedule is beyond Carbon's control. Carbon must wait for the pipeline to go back into service before Carbon can resume sale to CRC through the pipelines. Carbon currently has no other alternative means to dispose of the produced gas.

An interim variance is required for Carbon to maintain its existing operations, which include other wells in the Ojai Field Leases that are also affected by the SoCal Gas project, and to ensure that Carbon meets its financial obligations, including lease payments and remaining in business. If Carbon is not granted an interim variance, it will have to shut-in all the well casings to prevent further flaring of the produced gas until such time that permit authorizations allow further flaring (i.e., when higher months of flared gas drop off from the rolling 12-months), which will cause approximately \$100,000 in daily economic loss for Carbon for all of the affected fields as well as lost time for operations staff and contractors.

The Timber Canyon field produces approximately \$300,000 in revenue each month. This is approximately 12-percent of Carbon's total revenue for California productions. Combined with the shut-in of the Ojai Field Leases (that are also under force majeure) shutting in the wells would be detrimental to Carbon's business. If this variance (along with the Ojai variance petition) is not granted, 90-percent of Carbon's active wells would be shut in, which would put Carbon out of business because it would not be able to fulfill its financial obligations.

INTERIM VARIANCE ORDER NUMBER

Page 5

Furthermore, there are currently 11 Carbon field employees who work in the Ojai/Timber Canyon fields that would be laid-off if Carbon's pending interim variance petitions are not granted. Carbon operations also include approximately 15 support companies that provide services to the Ojai/Timber Canyon field operations.

The overall cost of continued shut-in would result in \$3 million per month loss for Carbon. This would be detrimental to its business, force employee layoffs and risk potential closure. Requiring immediate compliance would result in an unreasonable taking of property or the practical closing of a lawful business. Requiring immediate compliance would result in an unreasonable taking of property or the practical closing of a lawful business.

Carbon has given consideration to curtailing operations in lieu of obtaining a variance but for the following reasons it has been unable to do so: (1) the only option to flaring in this case is to shut-in the producing wells, (2) shutting in the producing wells, even temporarily, can result in a buildup of corrosion, scale, and, when the well is brought back online, there is a high risk of sand entering the well bore, which can cause mechanical problems with the pump, (3) the cost to correct each aforementioned issue can range from \$20,000 - \$40,000 per well and (4) there would also be additional exhaust emissions attendant to the servicing equipment that would be necessary to address.

Flaring is the only feasible solution that will reduce excess emissions to the maximum extent feasible during the variance period pursuant to District Rule 71.1.C, Crude Oil Production and Separation, Requirements - Produced Gas, which requires that emissions of produced gas shall be controlled at all times using a properly maintained and operated system that directs all produced gas, except gas used in a tank battery vapor recovery system, to one of the following: a fuel or sales gas system, a flare that combusts reactive organic compounds, or a device with an ROC destruction or removal efficiency of at least 90 percent by weight.

Carbon will continue monitoring of the flared gas via a Total Flow meter and quantify the emissions via emission factors for a flare. Carbon will submit flaring data to the District with weekly reports.

The flare at issue in this variance petition is located in a remote area north of the City of Santa Paula in Ventura County. The southern boundary of the oilfield is approximately 3 miles from the city. The closest residence to the flare has been reported to be 1.2 miles away and the closest school 2.85 miles away. A nuisance as specified in Rule 51 is not expected to occur during this flaring event. Continued operation is not likely to create an immediate threat or hazard to public health or safety.

FINDINGS OF FACT

The Hearing Board found that there was good cause to grant an interim variance because pursuant to Health and Safety Code Section 42352, and District Rule 123, "Findings, Variance or Abatement Order," the following findings have been made:

1. The petitioner is, or will be, in violation of Health and Safety Code Section 41701 or District Rule 29.C.
2. The violation is due to conditions beyond the reasonable control of the petitioner.
3. Requiring immediate compliance would result in either an arbitrary or unreasonable taking of property or the practical closing of a lawful business.
4. The closing or taking would be without a corresponding benefit in reducing air contaminants.
5. Petitioner has given consideration to curtailing operations in lieu of obtaining a variance.
6. Petitioner will reduce excess emissions to the maximum extent feasible during the variance period.
7. Petitioner will monitor or otherwise quantify emission levels from the equipment during the variance period, if requested to do so by the District, and report these emission levels to the District pursuant to a schedule established by the District.
8. A nuisance as specified in Rule 51 is not expected to occur.
9. Continued operation is not likely to create an immediate threat or hazard to public health or safety.

Further evidence shall be provided by the petitioner regarding items 2 through 9 at the noticed hearing that will be scheduled on or before November 22, 2019.

CONCLUSIONS AND ORDER

NOW, THEREFORE, the HEARING BOARD FINDS AND CONCLUDES THAT GOOD CAUSE HAS BEEN SHOWN AND ORDERS that Carbon is granted an Interim Variance from Rule 29, Conditions on Permits, Section C, Violation of Permit Condition 3 for its Clark and West Leases 18.0 MMBTU/hr Waste Gas Flare. This order will remain in effect until the Hearing Board holds a regular variance hearing and either

INTERIM VARIANCE ORDER NUMBER

Page 7

grants or denies the matter in Petition Number 879, or until compliance is demonstrated, whichever is sooner. A regular variance hearing will be scheduled on or before November 22, 2019. This variance is subject to the following conditions:

THE PETITIONER SHALL:

A. Increments of Progress

1. Carbon will continue monitoring of the flared gas via a Total Flow meter and quantify the emissions via emission factors for a flare. Carbon will submit flaring data to the District with weekly reports.
2. Carbon will provide weekly progress reports on the progress of CRC allowing Carbon's natural gas production back into the pipelines; the first report will be due by September 2, 2019.
3. Carbon will curtail gas production to the maximum extent feasible and notify the District which wells have been curtailed. Carbon will include details in weekly reports.
4. Carbon will attend a regular variance hearing on or before November 22, 2019.

B. Reporting Requirements

2. Carbon will monitor natural gas consumption during the variance and report this data to the District by December 9, 2019. Excess emissions and excess emission fees will be based on the data submitted in this report.
3. As required by District Rule 42.N, "Flaring Excess Emission Fee," payment of excess emission fees shall be submitted to the District no later than 60 days after receiving the bill.
4. All submittals and notifications to the District pursuant to this Variance Order shall be made to Ms. Michelle Wood, Ventura County Air Pollution Control District, 669 County Square Drive, Ventura, CA 93003.

C. General

1. Except as provided in this order, compliance with this Order shall not relieve Petitioner from liability under the District's Rules for any violation,

INTERIM VARIANCE ORDER NUMBER

Page 8

thereof, and shall not preclude the District from pursuing remedies in accordance with the Health and Safety Code in the event of any violation.

2. The failure to abide by any condition of this decision and Order shall subject Carbon to penalties set forth in Health and Safety Code Section 42402.
3. Each day during which a violation occurs is a separate offense.
4. Petitioner shall retain the obligation to comply with all other local, state and federal regulations not specifically referenced in this Variance Order.
5. Petitioner shall pay the Hearing Board fees specified in District Rule 41.

Board of Supervisors
County of Ventura
800 South Victoria Avenue
Ventura, California 93009

SUBJECT: Report Back and Seek Board Direction Regarding Potential Amendments to the County's Zoning Ordinances Regarding Oil and Gas Development; All Supervisorial Districts

RECOMMENDATIONS:

1. Receive and file report back regarding new oil and gas development under antiquated permits; and
2. Provide direction to County staff on potential amendments to the County's zoning ordinances to: (a) require discretionary approval of new oil and gas development; and (b) clarify the applicability of the County's oil development standards.

FISCAL/MANDATES IMPACTS: None.

DISCUSSION:

On April 9, 2019, the Board of Supervisors ("Board") gave two directions to staff. One, your Board directed staff to prepare an interim urgency ordinance for your Board's consideration regarding the drilling of new wells, and the re-drilling of existing wells, that would utilize steam injection in the vicinity of potable groundwater aquifers. On April 23 and June 4, 2019, your Board approved and then extended an interim urgency ordinance prohibiting County approval of such new oil wells, and the re-drilling of such existing wells, on a portion of the Oxnard Plain overlying the Fox Canyon aquifer. This interim urgency ordinance will remain in effect until December 7, 2019, unless further extended by your Board.

County of Ventura
Planning Commission Hearing
PL19-0003 and PL19-0041
Exhibit 24 - 9-10-19 Report to BOS re Potential
Amendments to Ordinances for Oil
and Gas Development

Two, your Board directed staff to “study potential amendments to the County’s zoning ordinances to require discretionary approval of new development under antiquated oil and gas permits.” The purpose of this Board item is to provide an overview of the legal issues and legislative options regarding this second recommendation, and seek direction for further actions, if any.

A. COUNTY PERMITTING OF OIL AND GAS DEVELOPMENT

1. County’s Antiquated Oil and Gas Permits

Oil and gas exploration and production activities and structures have been subject to a discretionary permitting requirement from the County since adoption of the County’s first zoning ordinance in 1947. Over time the County’s zoning ordinances and standard permits have become more stringent and detailed in their regulation of this land use. Approximately 125 County discretionary permits for oil and gas exploration and production are currently active.

From 1947 through approximately 1966, the County granted discretionary “special use permits” (the predecessor to the County’s “conditional use permits”) authorizing oil and gas exploration and production. These permits describe in very general terms the oil and gas-related activities and structures that are authorized within often large permit areas. They typically contain some variation of the following grant of authority:

Drilling for and extraction of oil, gas and other hydrocarbon substances and installing and using buildings, equipment, and other appurtenances accessory thereto, including pipelines, but specifically excluding processing, refining and packaging, bulk storage or any other use specified in Division 8, Ventura County Ordinance Code, requiring review and Special Use Permit.

The permits typically do not state the maximum number or exact location of allowable wells or other structures, nor do they contain expiration dates (i.e., dates by which the land use must end unless extended by the County). Because these permits were granted before enactment of the California Environmental Quality Act (“CEQA”) in 1970, none of the projects underwent CEQA review prior to initial permitting. The oil and gas permits granted by the County during this era are hereinafter referred to as “antiquated permits.” A representative antiquated permit is attached as Exhibit 1.

When a permittee seeks to add new wells or otherwise engage in new development under antiquated permits, the new development may only require a ministerial zoning clearance from the County.

2. County's Modern-Era Oil and Gas Permits

From approximately 1966 through the 1970's, the County utilized a new discretionary conditional use permit form with more detailed and stringent conditions as compared to the antiquated permits. The conditional use permits from this era typically only authorize the drilling and operation of a limited number of drill sites, wells and/or other structures; require discretionary County approval for all subsequent development; and contain permit expiration dates. Beginning in the early 1980's and continuing to present, the County's conditional use permits typically specify the exact number and location of all authorized wells and other appurtenant structures; impose more detailed and comprehensive conditions; and contain permit expiration dates.

When a permittee seeks to add new wells or otherwise engage in new development under conditional use permits granted by the County from approximately 1966 to present ("modern-era permits"), the new development typically requires a discretionary permit modification.

3. Ministerial Versus Discretionary Decisions

The distinction between ministerial and discretionary land use decisions is important to a full understanding of the County's regulation of oil and gas development. A ministerial decision is made by determining whether the request conforms to objective standards without the exercise of judgment or opinion by the decision-maker. In contrast, a discretionary decision is made by applying broader subjective standards through the exercise of judgment and opinion by the decision-maker. CEQA can apply to discretionary, but not to ministerial, land use decisions. Consequently, only discretionary permitting decisions can require some level of environmental review under CEQA. In addition, only discretionary permitting decisions involve the public noticing of, and a public hearing regarding, the permit request. Discretionary permitting decisions, unlike ministerial ones, also enable the County to impose permit conditions and mitigation measures to address environmental, land use compatibility, and other issues regarding the proposed development.

4. County's Approval of New Oil and Gas Development

Under the County's current zoning ordinances, a brand-new oil and gas development must be authorized by a discretionary conditional use permit. (See Non-Coastal Zoning Ordinance ["NCZO"], §§ 8105-4 and 8105-5, under heading "Mineral Resource Development," and subheading "Oil and Gas Exploration and Production"; Coastal Zoning Ordinance ["CZO"], § 8174-5, under heading "Oil and Gas: Exploration and Production.") Likewise, any material change to an existing modern-era oil and gas permit requires County discretionary approval in the form of a permit modification. (See NCZO, § 8111-6.1; CZO, § 8181-10.4.)

In contrast, requests to conduct new oil and gas development under active antiquated permits may only be subject to the County's ministerial zoning clearance process.¹ The primary standard for determining if a zoning clearance is to be issued in this context is whether the proposed development is consistent with and authorized by the underlying antiquated permit, and complies with the County's applicable zoning ordinance provisions and General Plan policies. (See NCZO, § 8111-1.1.1b; CZO, § 8181-3.1a). Making the permit consistency determination requires a fact-intensive analysis regarding each antiquated permit and zoning clearance request, which can be challenging given the age of the antiquated permits, potential uncertainty over a permit's status (i.e., whether it is active or has been abandoned), the fact that permit boundaries often overlap, and the fact that some antiquated permits may only authorize oil production at certain subsurface depths. Nonetheless, many new oil and gas development requests meet the consistency standard (and comply with applicable zoning provisions and General Plan policies) because, as explained above, antiquated permits typically broadly authorize oil and gas exploration and production structures and activities within the permit area.

Similarly, requests for new oil and gas development under antiquated permits often do not require a discretionary permit modification under the County's existing zoning ordinances because, unlike the County's more modern oil and gas permits (i.e., those granted from approximately 1966 to present), antiquated permits typically do not limit the number of wells and other structures, do not contain expiration dates, and do not contain other express limiting terms and conditions that must be changed in order to authorize the requested development. Consequently, the County often issues ministerial zoning clearances authorizing new oil and gas development under antiquated permits.

B. COUNTY'S ABILITY TO REQUIRE DISCRETINARY APPROVAL OF NEW DEVELOPMENT UNDER ANTIQUATED PERMITS

1. General Rule on Vested Rights

The County has a good legal argument that it can, in general, require newly proposed oil and gas development under antiquated permits to obtain authorization through a discretionary permit modification. Holders of antiquated permits may argue otherwise by claiming to possess vested rights to expand the oil and gas operations without the need for discretionary County approval. The County, however, has a good legal position that holders of typical antiquated permits generally do not have vested

¹ Some antiquated permits have been modified over time and now include more modern conditions, such as specific well limits and expiration dates. New development proposed under such modified permits typically must be approved through the discretionary permit modification process.

rights to engage in new oil and gas development based solely on the original antiquated permits, as explained below.²

Vested rights are based on a permittee's reasonable reliance on a government permit or approval describing a specific development project. Once a permittee has obtained the permit or approval, and has commenced work on the development, the government is estopped (i.e., prohibited) from preventing completion of the work pursuant to subsequently enacted legislation. The seminal California case on vested rights is *Avco Community Developers, Inc. v. South Coast Regional Commission* (1976) 17 Cal.3d 785 ("*Avco*").³

Under *Avco* and subsequent cases, a developer acquires a vested right to complete a particular work of improvement, regardless of a subsequent change in the law, when: (1) the appropriate government agency reviews, approves and issues a grant of authority or permit that specifically describes the particular work of improvement; and (2) the developer thereafter performs substantial work and expends substantial funds and/or incurs liabilities in good faith reliance on the grant or permit.

A permittee has the legal burden of establishing the existence and scope of vested rights. If a permittee establishes a vested right, the government may not, by virtue of a change in the laws, prohibit or impair development authorized by the permit or approval, unless the development presents a threat of harm, danger, menace or nuisance.⁴ Vested rights claims are fact-specific and determined on a case-by-case basis.

The above-stated requirement for a permit or approval to specifically describe the development project in order to create a vested right is a critical factor. The *Avco* court held that a governmental permit may only give rise to vested rights if the permit affords "substantially the same specificity and definition to a project as a building permit." (*Avco, supra*, 13 Cal.3d at p. 794.) *Avco's* "functional equivalent of a building permit"

² While the government can be found to have unlawfully impaired a permittee's vested rights merely by enacting a law subjecting a previously permitted development to a discretionary approval process, the permittee must possess vested rights in the proposed development in the first instance before it can be found that the government impaired vested rights in this way.

³ The court in *Avco* found the developer did not have vested rights despite spending millions of dollars in reliance on a final tract map and local zoning regulations. In response to the harsh effect *Avco's* holding had on developers, the Legislature authorized local governments to enter into binding development agreements with developers regarding project approvals. (See Gov. Code, §§ 65864 et seq.)

⁴ Even when a permittee has established vested rights, the County possesses constitutional land use authority to regulate the subject development, including by requiring compliance with most of the County's oil development standards, as explained below.

requirement is based on balancing the developer's need for certainty regarding its development proposal without unduly impairing the government's ability to address environmental concerns and regulate land use. The federal Ninth Circuit Court of Appeals has summarized this balance as follows:

"If the public is to be deprived of its power to control pollution and other problems caused by overdevelopment, it should be deprived only to the extent necessary to ensure private parties a reasonable degree of certainty about the legal status of their investments." (*Lakeview Dev. Corp. v. City of S. Lake Tahoe* (9th Cir. 1990) 915 F.2d 1290, 1299.)

2. Lack of Specificity

Given the typical antiquated permits' lack of specificity regarding the scope and composition of the development authorized by the permits, the County has a good argument the permits no longer confer vested rights to engage in *new* development. Again, these permits do not state the number or exact location of any wells or other structures that are authorized by the permits; instead, they generally authorize the permittee to conduct oil and gas exploration and production activities within the permit area. The permits are thus analogous to general zoning designations – which do not give rise to vested rights – in that they generally allow a land use to occur within an often-large area without specifying the details of a specific facility, structure, equipment or operation. Consequently, holders of these permits cannot cite to any particularly described oil and gas project as being authorized by the permits in order to satisfy this critical vested rights requirement.

On the other hand, permittees have a good position that they have acquired vested rights to continue operating *existing* oil and gas facilities that have been developed pursuant to antiquated permits. Even though the antiquated permits themselves do not specifically describe the projects that may be developed under the permits, the County has long required permittees to obtain a zoning clearance and/or building permit for each new well and related structure. Permittees with antiquated permits presumably possess vested rights to continue operating such equipment as particularly described in these zoning clearances and/or building permits in accordance with *Avco*. Permittees also have a good position that they possess vested rights to continue operating oil facilities that were lawfully established before the County began requiring a CUP, zoning clearance and/or building permit.

3. Time Period for Development

Even if vested rights in a permit are acquired, a lengthy delay by the permittee to proceed with the project on a pace reasonably close to that contemplated when the project was approved may cause the vested rights to be lost. If, contrary to our view,

broadly worded antiquated permits did convey vested rights to engage in some level of oil and gas development once perfected (absent subsequently issued zoning clearances and/or building permits more particularly describing the associated structures), the County has a good argument that the time periods for permittees to exercise these rights by building out new development under the initial antiquated permits have now expired. The antiquated permits were granted between approximately 53 and 72 years ago. Thus, permittees have had decades to build out the oil and gas projects under the initial approvals. The County has a good argument that permittees are not entitled to construct any new oil and gas development, without first obtaining discretionary County approval, because the permittees' vested rights have lapsed through unreasonable delay in completing the initially approved projects.

4. Prior County Counsel Opinion

In 2014, County Counsel addressed the issue of vested rights and antiquated permits in a memorandum attached as Exhibit 2. The issue then presented was the County's authority to impose new conditions on *existing* oil and gas operations subject to antiquated permits. For purposes of addressing that specific issue, the memorandum assumes that permittees possess some level of vested rights in antiquated permits and proceeds to explain how such vested rights constrain the County's ability to impose new permit conditions on the *existing* operations. The memorandum does not, however, address the threshold issue now presented: Whether typical antiquated permits – i.e., those with broad authorizing language that do not specify the number and location of allowable wells or other structures – give rise to vested rights in and of themselves. For the reasons stated above, County Counsel believes they typically do not.

This vested rights issue is nuanced. Even though typical antiquated permits do not confer vested rights to engage in *new* development for the reasons stated above, permittees who have developed oilfield facilities under them have presumably obtained vested rights in their *existing* wells and other structures. Consequently, the 2014 County Counsel memorandum accurately recognizes permittees' presumptive vested rights in *existing* oilfield facilities and explains how these vested rights constrain the County's ability to impose new conditions on *existing* operations.

C. POTENTIAL ZONING ORDINANCE AMENDMENTS

1. Requiring Discretionary Approval of New Development under Antiquated Permits

The County's zoning ordinances contain specific regulations for oil and gas exploration and production. (NCZO, § 8111-5; CZO, § 8175-5.7.) These regulations could be amended to require a discretionary permit modification to authorize new development proposed under typical antiquated permits, and any other discretionary County permits, that do not specifically describe and authorize the newly proposed

oilfield structures. This discretionary permit modification requirement would be in addition to the County's existing permit modification requirement which, as explained above, applies whenever a permittee seeks to change the terms and conditions of an existing discretionary permit.

Applying the County's discretionary permit modification process to new development proposed under antiquated permits would require some level of CEQA review of the proposed development and the provision of public notice and a public hearing by the County's decision-making authority regarding the request. In order to approve the proposed development, the County's decision-making authority would need to find that the proposed development meets the County's general permit approval standards (see NCZO, § 8111-1.2.1.1a; CZO, § 8181-3.5) including, among others, that the proposed development would not be detrimental to the public interest, health, safety, convenience, or welfare; would not be obnoxious or harmful; and is compatible with existing and potential land uses in the general area.

This discretionary permitting process would thereby provide the County with the ability to: (1) fully investigate and publicly disclose the potential environmental impacts of the proposed development under CEQA; (2) weigh the merits of the proposed development against its potential negative impacts in deciding whether to approve the new development; and (3) impose permit conditions on approved development to mitigate potential environmental impacts and to address relevant land use issues, including conditions developed pursuant to the County's oil development guidelines and design standards set forth at NCZO section 8107-5.5 and CZO section 8175-5.7.7.

2. Clarifying Applicability of County's Oil Development Standards

The County's oil and gas regulations could also be amended to clarify another issue implicated by antiquated permits: the applicability of the County's oil development standards. These standards regulate various operational issues such as well and equipment siting, grading, lighting, waste handling, noise, site maintenance and site restoration. (See NCZO, § 8107-5.5; CZO, § 8175-5.7.8.) The County's current zoning ordinances state that the oil development standards apply to "permits" granted or modified by the County on or after March 24, 1983, the date upon which many of the County's current oil and gas standards were adopted. However, it is sometimes not clear what County oil development standards apply to oilfield structures and operations conducted pursuant to permits granted or issued before March 24, 1983.

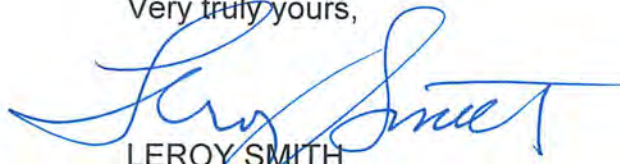

This issue can be clarified by amending the County's zoning ordinances to state that the County's oil development standards uniformly apply to all oil and gas exploration and production operations to the extent: (i) such standards would impose more stringent restrictions than those set forth in existing permit conditions, laws, or regulations applicable to the operation; and (ii) application of such standards would not impair any vested right of an operator under California law. The latter vested rights

exception is needed because certain oil development standards, such as the oil structure siting and setback requirements, could not be applied to existing facilities without potentially impairing a permittee's vested rights.

These potential zoning ordinance amendments are reflected in a draft revised version of NCZO section 8107-5.2 attached as Exhibit 3, which can be compared to the existing version of this section attached as Exhibit 4. This NCZO section, and its counterpart at section 8175-5.7.2 in the CZO, address the applicability of the County's oil and gas regulations.

This board item has been reviewed by the County Executive Office, the Auditor-Controller's Office and the Resource Management Agency Planning Division. If you have any questions, please call me at (805) 654-2581.

Very truly yours,

LEROY SMITH
County Counsel

The 2013–2016 induced earthquakes in Harper and Sumner Counties, southern Kansas

Bulletin of the Seismological Society of America

By: Justin L. Rubinstein  , William L. Ellsworth  , and Sara L. Dougherty

Abstract

We examine the first four years (2013–2016) of the ongoing seismicity in southern Kansas using high-precision locations derived from a local seismometer network. The earthquakes occur almost exclusively in the shallow crystalline basement, below the wastewater injection horizon of the Arbuckle Group at the base of the sedimentary section. Multiple lines of evidence lead us to conclude that disposal of wastewater from the production of oil and gas by deep injection is the probable cause for the surge of seismicity that began in 2013. First, the seismicity correlates in space and time with the injection. We observe increases in seismicity subsequent to increases in injection and decreases in seismicity in response to decreases in injection. Second, the

earthquake-rate change is statistically improbable to be of natural origin. From 1974 through the time of the injection increase in 2012, no M_L 4 or larger earthquakes occurred in the study area, while six occurred between 2012 and 2016. The probability of this rate change occurring randomly is $\sim 0.16\%$. Third, the other potential industrial drivers of seismicity (hydraulic fracturing and oil production) do not correlate in space or time with seismicity. Local geological conditions are important in determining whether injection operations will induce seismicity, as shown by absence of seismicity near the largest injection operations in the southwest portion of our study area. In addition to local operations, the presence of seismicity 10+ km from large injection wells indicates that regional injection operations also need to be considered to understand the effects of injection on seismicity.

EXHIBIT 15

Studies link earthquakes to fracking in the Central and Eastern US

Date: April 26, 2019

Source: Seismological Society of America

Summary: Small earthquakes in Ohio, Pennsylvania, West Virginia, Oklahoma and Texas can be linked to hydraulic fracturing wells in those regions, according to researchers.

FULL STORY

Small earthquakes in Ohio, Pennsylvania, West Virginia, Oklahoma and Texas can be linked to hydraulic fracturing wells in those regions, according to researchers speaking at the SSA 2019 Annual Meeting.

While relatively rare compared to earthquakes caused by wastewater disposal in oil and gas fields in the central United States, Michael Brudzinski of Miami University in Ohio and his colleagues have identified more than 600 small earthquakes (between magnitude 2.0 and 3.8) in these states.

Brudzinski said these earthquakes may be "underappreciated" compared to seismicity related to wastewater disposal since they appear to happen less frequently. He and his colleagues are studying the trends related to the likelihood of induced seismicity from hydraulic fracturing or fracking, which could help industry and state regulators better manage drilling practices.

Unconventional U.S. oil production, which extracts oil from shales and tight rocks using a variety of drilling techniques, has been linked to an increase in human-induced earthquakes across the mid-continent of the United States for nearly a decade. Researchers studying the increase in places such as Oklahoma think that the main driver of this increase in seismicity is the injection of wastewater produced by extraction back into rock layers, which increases pore pressure within rocks and can affect stress along faults in layers selected for disposal.

Hydraulic fracturing uses pressurized liquid to break apart or create cracks within a rock formation through which petroleum and natural gas can flow and be more easily extracted.

In the eastern half of Ohio and other parts of the Appalachian Basin, where there has been a dramatic rise in natural gas production over the past two decades, fracking wells are more prevalent than wastewater disposal wells, in part because the geological layers that contain oil and gas are not as wet as in places like Oklahoma, reducing the need for wastewater disposal.

The numerous fracking wells in eastern Ohio prompted Brudzinski and his colleagues to take a closer look at whether small earthquakes in the region could be connected to fracking operations. "The wells are more widely spaced when they're active, and there isn't as much wastewater disposal going on," Brudzinski explained, "so you can see a bit more specifically and directly when wastewater disposal is generating seismicity and when hydraulic fracturing is generating seismicity in the Appalachian Basin."

The scientists used a technique called multi-station template matching, which scans through hundreds of seismic signals to find those that match the "fingerprint" of known earthquakes. The technique allowed them to detect small earthquakes that might have otherwise been overlooked, and to compare the more complete earthquake catalog in a region to information on the timing and location of regional fracking well operations.

Seismologists identify earthquakes as being caused by hydraulic fracture wells when they are tightly linked in time and space to fracking operations. Fracking-related seismicity also tends to look different from seismicity caused by wastewater disposal, Brudzinski said.

"The [fracking] seismic signature when you look at it in a sort of timeline shows these bursts of seismicity, hundreds or sometimes thousands of events over a couple of days or weeks, and then it's quiet again. You don't tend to see that pattern with wastewater disposal," he explained.

Brudzinski and his colleagues are now using their dataset from Oklahoma to look at how a variety of variables might affect the likelihood of fracking-induced earthquakes, from the volume and viscosity of the injected liquid to the depth of the rock layers targeted by fracking.

"The one that has stuck out to us the most is that the depth of the well is more tied to likelihood of seismicity than we expected," Brudzinski said.

It isn't just the deeper the well, the more likely it is to be closer to basement rock and mature faults that are likely to slip, he said, although that might still play a role in these earthquakes. Instead, overpressuring appears to have a stronger correlation with fracking-induced seismicity. Overpressuring occurs when there is high fluid pressure within rocks buried deep in a basin by many overlying rock layers. "It's one of the strongest trends we saw," said Brudzinski.

The researchers have discussed some of their findings with colleagues in Canada and China, where induced seismicity from fracking operations are being studied closely. "We are doing that kind of international comparison to get a better handle on the salient features and trends that aren't just tied to a specific location," said Brudzinski.

Compendium of Scientific, Medical, and Media Findings Demonstrating Risks and Harms of Fracking (Unconventional Gas and Oil Extraction)

Sixth Edition

June 2019

Fracking rigs off of Interstate 20
West of Midland, Texas, in the Permian Basin ©2018 Julie Dermansky

The Compendium of Scientific, Medical, and Media Findings Demonstrating Risks and Harms of Fracking (the Compendium) is a fully referenced compilation of evidence outlining the risks and harms of fracking. It is a public, open-access document that is housed on the websites of Concerned Health Professionals of New York (www.concernedhealthny.org) and Physicians for Social Responsibility (www.psr.org).

The five earlier editions of the Compendium have been used and referenced all over the world. The Compendium has been twice translated into Spanish: independently in 2014 by a Madrid-based environmental coalition, followed by an official translation of the third edition, which was funded by the Heinrich Böll Foundation and launched in Mexico City in May 2016. The Compendium has been used in the European Union, South Africa, the United Kingdom, Australia, Mexico, and Argentina.

About Concerned Health Professionals of New York

Concerned Health Professionals of New York (CHPNY) is an initiative by health professionals, scientists, and medical organizations for raising science-based concerns about the impacts of fracking on public health and safety. CHPNY provides educational resources and works to ensure that careful consideration of science and health impacts are at the forefront of the fracking debate.

About Physicians for Social Responsibility

Working for more than 50 years to create a healthy, just, and peaceful world for both present and future generations, Physicians for Social Responsibility (PSR) uses medical and public health expertise to educate and advocate on urgent issues that threaten human health and survival, with the goals of reversing the trajectory towards climate change, protecting the public and the environment from toxic chemicals, and addressing the health consequences of fossil fuels. PSR was founded by physicians concerned about nuclear weapons, and the abolition of nuclear weapons remains central to its mission.

About this Report

The Compendium is organized to be accessible to public officials, researchers, journalists, and the public at large. The reader who wants to delve deeper can consult the reviews, studies, and articles referenced herein. In addition, the Compendium is complemented by a fully searchable, near-exhaustive citation database of peer-reviewed journal articles pertaining to shale gas and oil extraction, the Repository for Oil and Gas Energy Research, that was developed by PSE Healthy Energy and which is housed on its website (<https://www.psehealthyenergy.org/our-work/shale-gas-research-library/>).

For this sixth edition of the Compendium, as before, we collected and compiled findings from three sources: articles from peer-reviewed medical or scientific journals; investigative reports by journalists; and reports from, or commissioned by, government agencies. Peer-reviewed articles were identified through databases such as PubMed and Web of Science, and from within the PSE Healthy Energy database. We included review articles when such reviews revealed new understanding of the evidence.

Written in non-technical language, our entries briefly and plainly describe studies that document harm, or risk of harm, associated with fracking and summarize the principal findings. Entries do not include detailed results or a critique of the strengths and weaknesses of each study. Because much of medicine's early understanding of new diseases and previously unsuspected epidemiological correlations comes through assessment of case reports, we have included published case reports and anecdotal reports when they are data-based and verifiable.

The studies and investigations referenced in the dated entries catalogued in the Compilation of Studies & Findings are current through April 1, 2019. The footnoted citations here in the front matter represent studies and articles that are not referenced in the Compendium itself or which appeared as we went to press in June 2019.

Within the compiled entries, we have also provided references to articles appearing in the popular press, when available, that describe the results of the corresponding peer-reviewed study and place them in context with the results of other studies. For this purpose, we sought out articles that included comments by principal investigators on the significance of their findings. In such cases, footnotes for the peer-reviewed study and the matching popular article appear together in one entry. We hope these tandem references will make the findings more meaningful to readers.

Acronyms are spelled out the first time they appear in each section.

News articles appearing as individual entries signify reports that contain original research. In many cases, this reportage is based on data collected by industry or government agencies that were ferreted out by investigative journalists and not otherwise known to the scientific community.

While advocacy organizations have compiled many useful reports on the impacts of fracking, these, with few exceptions, do not appear in our Compendium unless they provide otherwise inaccessible data. We also excluded papers that focused purely on methodologies or instrumentation. For some sources, cross-referenced footnotes are provided, as when wide-

ranging government reports or peer-reviewed papers straddled two or more topics.

In our review of the data, seventeen compelling themes emerged, and these serve as the organizational structure of the Compendium. Readers will notice the ongoing upsurge in reported problems and health impacts, making each section top-heavy with recent data. In accordance, the Compendium is organized in reverse chronological order within sections, with the most recent information first.

The Compendium focuses on topics most closely related to the public health and safety impacts of unconventional gas and oil drilling and fracking. These necessarily include threats to climate stability.

Additional risks and harms arise from associated infrastructure and industrial activities that necessarily accompany drilling and fracking operations. A detailed accounting of all these ancillary impacts is beyond the scope of this document. Nevertheless, we include in this edition a section on impacts from fracking infrastructure that focuses on

- compressor stations and pipelines;
- silica sand mining operations;
- natural gas storage facilities;
- the manufacture and transportation of liquefied natural gas (LNG), and
- natural gas power plants.

(Research on gas-fired power plants appears in this edition for the first time. Note that threats from flare stacks are included in the section on air pollution.)

Many other relevant concerns—such as disposal of solid waste drill cuttings and the use of fracked gas as a feedstock in petrochemical manufacturing—are not included here. We hope to take up these issues in future editions.

Similarly, this edition of the Compendium does not examine the harms and risks posed by other forms of unconventional oil and gas extraction, such as cyclic steaming (which uses pressurized, superheated water to release oil), microwave extraction (which points microwave beams into shale formations to liquefy oil), and artificial lift (which uses gases, chemicals, or pumps to extract natural gas).

Given the rapidly expanding body of evidence related to the harms and risks of unconventional oil and gas extraction, we plan to continue revising and updating the Compendium approximately every year. It is a living document, housed on the websites of Concerned Health Professionals of New York and Physicians for Social Responsibility, which serves as an educational tool in important ongoing public and policy dialogues.

The Compendium is generally a volunteer project and has no dedicated funding; it was written utilizing the experience and expertise of numerous health professionals and scientists who have been involved in this issue for years.

Foreword to the Sixth Edition

The Compendium in Historical Context

The release of the first edition of the Compendium by Concerned Health Professionals of New York in July 2014 coincided with a meteoric rise in the publication of new scientific studies about the risks and harms of fracking. A second edition was released five months later, in December 2014, and included new studies that further explicated recurrent problems.

Almost concurrently, on December 17, 2014, the New York State Department of Health (NYS DOH) released its own review of the public health impacts of fracking. (See footnote 655.) That document served as the foundation for a statewide ban on high-volume hydraulic fracturing (HVHF), announced by New York Governor Andrew Cuomo on the same day. Its conclusions—

[I]t is clear from the existing literature and experience that HVHF activity has resulted in environmental impacts that are potentially adverse to public health. Until the science provides sufficient information to determine the level of risk to public health from HVHF and whether the risks can be adequately managed, HVHF should not proceed in New York State.

The third edition of the Compendium, released in October 2015 and compiled as a joint effort with Physicians for Social Responsibility, included new peer-reviewed studies as well as the results of the first substantive government reports on the impacts of fracking. One of these was the New York State Department of Environmental Conservation's final environmental impact statement and attendant Findings Statement that incorporated the earlier health review into a larger analysis of the impacts of fracking. (See footnote 482.) The Findings Statement made clear that no known regulatory framework can adequately mitigate the multiple risks of fracking:

Even with the implementation of an extensive suite of mitigation measures...the significant adverse public health and environmental impacts from allowing high-volume hydraulic fracturing to proceed under any scenario cannot be adequately avoided or minimized to the maximum extent practicable....

In December 2015, the third edition became the basis of invited testimony at conferences taking place concurrently with the United Nations' climate talks in Paris. Those international negotiations resulted in an historical international accord, the Paris Agreement, which recognizes climate change as a grave threat to public health and establishes as a key goal the need to limit global temperature increases to 2° Celsius, or, ideally, 1.5° C, above pre-industrial times. As such, the treaty articulates a vision for energy by compelling nations to monitor their greenhouse gas emissions and set increasingly ambitious targets and timetables to reduce them.

The Compendium's fourth edition was released in November 2016, just as the Paris Agreement went into force and as several new studies conclusively demonstrated that expansion of shale gas and oil extraction was incompatible with climate stability and the goal of rapid decarbonization that it requires. All together, these data show that because of increasing emissions of methane—a powerful heat-trapping gas—the United States was on track to miss its pledge under the Paris Agreement to reduce greenhouse gas emissions 26-28 percent by 2025. (See footnotes 977 and

978.) The evidence showed that methane leaks from U.S. oil and gas operations were significantly higher than previously estimated, as were U.S. methane emissions overall. (See footnotes 979-981, 987, 998, and 999.)

The fifth edition, released in March 2018, was launched in a time of deep environmental retrenchment by the U.S. government. The Trump administration had announced an era of “energy dominance” based on surging domestic production of oil and natural gas, most of it extracted via fracking. References to climate change were removed altogether from some government websites. Greenhouse gas emissions were no longer to be considered in National Environment Policy Act reviews. The White House announced its intent to withdraw from the Paris Agreement even as the American Meteorological Society released a major report that identified climate change as a contributor to several recent extreme weather events and even as the Fourth National Climate Assessment—a quadrennial report compiled by 13 federal agencies—confirmed human activities as the dominant cause for ongoing global warming.^{1,2}

Included in the federal environmental rules rescinded during this period were many that governed drilling and fracking operations. The Bureau of Land Management’s (BLM) Waste Prevention Rule, requiring companies drilling on public and tribal lands to reduce methane leaks and cut back on flaring and venting, was suspended. The U.S. Environmental Protection Agency (EPA) canceled a system for existing oil and gas facilities to report methane leaks and delayed implementation of a rule that would have limited methane emissions from new oil and gas drilling sites. The U.S. Department of the Interior rescinded a rule to require disclosure of chemicals in fracking fluid on public lands and tighten standards for well construction and wastewater disposal. The White House revoked policies that had prevented the construction of the Dakota Access Pipeline. That pipeline now carries fracked oil from the Bakken Shale in North Dakota to an oil storage hub in Illinois.^{3,4}

This current sixth edition of the Compendium arrives at a time of starkly contradictory trends.

On the one hand, aggressive attacks on regulatory oversight of U.S. oil and gas extraction continue and now extend to the science underlying the targeted regulations. A recent EPA directive has banned scientists who received EPA funding from sitting on panels that advise the agency on scientific matters.⁵ An order issued by the White House-appointed director of the U.S.

Geological Survey (USGS) now prohibits that agency's scientists from generating climate models beyond the year 2040.⁶

The feverish pace of U.S. oil and gas extraction also continues. Unimpeded by federal regulations and driven by fracking, U.S. oil and gas production has reached record levels, which, in turn, has spurred a massive build-out of fracking infrastructure. The Federal Energy Regulatory Commission (FERC) has eased the process to build new pipelines, and even more public lands have been opened to oil and gas extraction.⁷ One executive order has impeded the ability of states to block pipeline construction, while another has transferred power for international pipeline approval from the U.S. State Department to the President.⁸ As the U.S. Energy Information Administration (EIA) forecasts record build-out of natural gas pipelines, the Pipeline and Hazardous Materials Safety Administration (PHMSA) has urged Congress to expand a law that treats some kinds of citizen protests against pipeline construction as federal crimes.⁹

The White House policy of energy dominance also continues apace. In the face of flattening domestic demand for gas, the ongoing fracking boom is increasingly directed at export markets.¹⁰ The United States is on track to become the world's largest international seller of natural gas. As of this writing, three liquefied natural gas (LNG) export terminals are operational with more than a dozen new LNG terminals in the planning or development stage. Exports of LNG from the United States to the European Union alone have increased by 181 percent since July 2018.¹¹ In May 2019, the U.S. Department of Energy introduced the terms "freedom gas" and "molecules of U.S. freedom" to refer to LNG exports.¹² In June 2019, as we went to press, the Delaware River Basin Commission approved a plan to construct an LNG terminal on the Delaware River in Gibbstown, New Jersey with the aim of exporting natural gas extracted from shale gas wells in Pennsylvania.^{13, 14} The gas would be trucked to the export terminal from a new LNG liquefaction plant planned for Pennsylvania's Bradford County.¹⁵

Similarly, by September 2018, the United States had become the world's leading oil producer, surpassing both Russia and Saudi Arabia.¹⁶ U.S. oil production is forecast to increase by 30 percent by 2023, with much of that growth driven by fracking operations in the Permian Basin of West Texas and eastern New Mexico. The Permian is now the leading source of U.S. crude oil exports.¹⁷

On the other hand, the ongoing U.S. fracking boom and its protracted deregulation are at odds with the emerging scientific consensus on the scale and tempo of necessary climate change mitigation and with rising public alarm about the impending climate crisis that this consensus has amplified. In some cases, Trump-era rollbacks have been reversed. In March 2019, a U.S. district judge blocked leasing of public lands for fracking in Wyoming on the grounds that the BLM had not considered greenhouse gas emissions.¹⁸ (Physicians for Social Responsibility was a party to this lawsuit.) The National Aeronautics and Space Administration's (NASA) Carbon Monitoring System, targeted by the White House for elimination in 2018, was refunded by Congress in 2019.¹⁹

In October 2018, in its first commissioned report under the Paris Agreement, the United Nations Intergovernmental Panel on Climate Change (IPCC) announced that emissions from oil and gas must decline swiftly within the next decade—a trend not compatible with further build-out of oil and gas infrastructure. Specifically, the IPCC found that global warming above 1.5° C is likely to result in irreversible points of no return and cascading, uncontrollable harms, including wholesale loss of coral reefs, loss of ocean fish stocks, widespread crop failures, flooding of coastal cities, multiple public health crises, and social disruption. To avoid the worst of these outcomes, the world needs to reduce greenhouse gas emissions by 45 percent by 2030 and reach net zero by 2050.^{20, 21}

These findings were confirmed and expanded upon in another landmark paper published in April 2019 by an international team of scientists who warned that “it has become clear that beyond 1.5° C, the biology of the planet becomes gravely threatened because ecosystems literally begin to unravel.”²²

In May 2019, a joint appeal from the leaders of the United Nations System organizations urged world political leaders “with great urgency” to accelerate mitigation efforts in order to limit the global temperature to 1.5° C above pre-industrial levels, referring to this limit as a “moral, economic imperative.”²³

The ongoing fracking boom is also at odds with trends in the economics of renewable energy. The ongoing build-out of natural gas pipelines has been accompanied by an ongoing wave of natural gas power plant construction across the United States. In 2018, 35 percent of electricity in the United States was generated in gas-fired power plants—a figure that is forecast to rise to 38 percent by 2020.²⁴ At the same time, rapid declines in the cost of wind, solar, and battery storage prices have now made renewable energy a cheaper alternative than coal and gas in most major economies.²⁵ A new analysis shows that a 100 percent renewable energy system in the United States would reduce electricity costs.²⁶

Indeed, renewables are already replacing existing gas plants in some cases. In 2018, three large gas-fired power plants closed in California, with more retirements planned as wind and solar replace gas for electrical generation.^{27, 28} In March 2019, Florida Power and Light announced it would retire two natural gas plants and replace them with a massive solar-powered battery bank.²⁹ In April 2019, Indiana regulators rejected a proposal to replace three retiring coal plants

²⁹ Geuss, M. (2019, March 29). Florida utility to close natural gas plants, build massive solar-powered battery. *Ars Technica*. Retrieved from <https://arstechnica.com/information-technology/2019/03/florida-utility-to-close-natural-gas-plants-build-massive-solar-powered-battery/>

with a massive natural gas plant over concerns that gas was a risky investment “if alternatives decline in price.”³⁰

With an economic lifespan of between 30 and 50 years, new gas and oil infrastructure projects are now at risk for becoming stranded assets. Evidence shows that, even in the absence of new climate policies, continuing investments in fossil fuel exports may substantially harm the U.S. economy.³¹

Expanding Knowledge Base

Even as we compiled entries for this sixth edition, the authors of the Compendium continued to see evidence of, and appreciate, the rapid expanse of our knowledge base. The Compendium exists within a moving stream of data.

As is revealed in the Repository for Oil and Gas Energy Research (ROGER), the database of literature maintained by PSE Healthy Energy, the number of peer-reviewed publications relevant to assessing the environmental, socioeconomic, and public health impacts of shale gas development doubled between 2011 and 2012. It doubled again between 2012 and 2013.³²

This trend continues. More than half of the peer-reviewed scientific papers on the risks and harms of fracking have been published since January 2016. Indeed, 20 percent (355 studies) of the now more than 1,700 available studies were published in 2018 alone.

As of April 16, 2019, there were 1,778 published peer-reviewed studies that pertain to shale and tight gas development archived in the ROGER database.³³

This body of evidence clearly reveals both potential and actual harms. Specifically, PSE’s statistical analysis of the scientific literature available from 2009 to 2015 demonstrates that:

- 69 percent of original research studies on water quality found potential for, or actual evidence of, fracking-associated water contamination,
- 87 percent of original research studies on air quality found significant air pollutant emissions, and
- 84 percent of original research studies on human health risks found signs of harm or indication of potential harm.³⁴

³⁰ Bade, G. (2019, April 25). Indiana regulators reject Vectren gas plant over stranded asset concerns. *Utility Dive*. Retrieved from <https://www.utilitydive.com/news/indiana-regulators-reject-vectren-gas-plant-over-stranded-asset-concerns/553456/>

³² PSE Healthy Energy (2016, April 20). The science on shale gas development [infographic]. Retrieved from http://www.psehealthyenergy.org/data/PSE_FrackingStudy_Summary_Infographic_4-20-2016_00.jpg

³³ PSE Healthy Energy. Repository for Oil and Gas Research (ROGER). <https://www.psehealthyenergy.org/our-work/shale-gas-research-library/>

A follow-up analysis using the same criteria for inclusion found that 90.3 percent of all original research studies published from 2016-2018 on the health impacts of fracking found a positive association with harm or potential harm.³⁵

Timeline of Bans and Moratoria

As a response to the proliferating evidence of the risks and harms of fracking—augmented by increasing concern about the many remaining uncertainties—various countries, states, and municipalities have instituted bans and moratoria.

France banned fracking in July 2011 and Bulgaria in January 2012.

In May 2012, the state of Vermont banned fracking and prohibited the storage and treatment of fracking waste.

In July 2012, a revision of environmental laws in Austria prompted the main Austrian oil and gas group to announce a stop to its shale gas plans in the country.

In April 2013, the Luxembourg parliament passed a motion against shale gas exploration in a decision that has not been revisited since.

In July 2014, the Flanders region of Belgium temporarily banned fracking. This ban is still valid.

The California counties of Santa Cruz, San Benito, and Mendocino counties all banned fracking in 2014.

New York State banned fracking in December 2014.

In January 2015, Scotland became the first country in Great Britain to impose a formal moratorium on fracking. In 2016, as part of the ongoing moratorium process, the government of Scotland released a series of reports that reconfirmed the evidence for potential contamination of air and water, threats to worker health from silica dust exposure, and risks to the health of nearby residents. It further noted that the pursuit of unconventional oil and gas extraction would make it more difficult for Scotland to achieve its climate targets on greenhouse gas emissions.^{36, 37}

Scotland's moratorium was extended "indefinitely" in October 2017. In March 2019, a decision to solidify that prohibition into a full legislative ban was delayed.

³⁴ Hays, J., & Shonkoff, S. B. C. (2016). Toward an understanding of the environmental and public health impacts of shale gas development: An analysis of the peer-reviewed scientific literature, 2009-2015. *PLOS One*, *11*(4), e0154164. doi: 10.1371/journal.pone.0154164

In February 2015 the government of Wales declared a moratorium on fracking “until it is proven safe.” In July 2018, the Welsh government confirmed that shale gas was not compatible with decarbonization targets and said it would not support applications for fracking.

In March 2015, the Canadian province of New Brunswick declared a moratorium on fracking.

In July 2015, the Netherlands banned all shale gas fracking until 2020 on the grounds that “research shows that there is uncertainty” about impacts. In October 2018, the Dutch government announced that gas extraction of all kinds in the Groningen gas field would entirely cease by 2030 after public outcry over continuing earthquakes in the region. Gas production has already been cut by 60 percent since its peak in 2013. On May 22, 2019, Groningen was hit with a magnitude 3.4 earthquake that damaged multiple homes.³⁸

In September 2015, Northern Ireland effectively banned fracking via strategic planning policies.

In December 2015, the plenary of the European Parliament affirmed the incompatibility of shale gas extraction via hydraulic fracturing with the European Union’s commitment to decarbonization, and it acknowledged public concerns about the environmental and health impacts of fracking. While falling short of an outright EU-wide moratorium on fracking, the report states that “it is questionable whether hydraulic fracturing can be a viable technology in the European Union.”³⁹

In Florida, 90 municipalities have either banned fracking outright or passed resolutions opposing it. In the past three legislative sessions, a bipartisan coalition of lawmakers has introduced statewide ban legislation. During his 2018 campaign, Governor Ron DeSantis pledged publicly to issue a statewide ban. As of this publication, he has yet to do so.

Also in 2016, New Brunswick extended its moratorium on fracking “indefinitely,” citing unresolved problems with the disposal of fracking wastewater, and in the Canadian province of Newfoundland and Labrador, where a moratorium had been in place since 2013, a government-appointed panel recommended that fracking remain “paused,” citing data gaps and unresolved questions about the underlying geology.

In June 2016, Germany adopted a moratorium on “unconventional fracking” until 2021 but will permit exploratory drilling research projects.

Also in 2016, California’s Butte and Alameda counties banned fracking, along with Monterey County, which also banned all new oil drilling.

In August 2016, the Australian state of Victoria declared a permanent ban on fracking on the grounds that the risks outweighed any potential benefits.

³⁸ (2019, May 22). Groningen hit by strong earthquake as gas extraction impact continues. *DutchNew.nl*. Retrieved from <https://www.dutchnews.nl/news/2019/05/groningen-hit-by-strong-earthquake-as-gas-extraction-impact-continues/>

³⁹ Committee on Industry, Research and Energy. (2015, November 24). *Report on Towards a European Energy Union*, A8-0341/2015. Retrieved from <http://www.europarl.europa.eu/sides/getDoc.do?pubRef=-//EP//TEXT+REPORT+A8-2015-0341+0+DOC+XML+V0//EN>

In September 2016, a California judge, arguing that the agency had failed to consider the dangers of fracking, struck down a bid by the BLM to open one million acres of public land in central California to oil drilling.

In November 2016, Winona County, Minnesota banned the mining of frack sand, a decision that was upheld in district court in November 2017. That ruling is now before the Minnesota Supreme Court.⁴⁰

In December 2016, the Portland City Council in Oregon approved zoning code changes that banned the construction of new fossil fuel projects, including terminals for storing and transporting natural gas, and also prohibited the expansion of pre-existing facilities, including an LNG plant.

In March 2017, the Spanish region of Castilla Leon signed a political agreement to give up on shale gas exploration. This decision followed the implementation of several other regional bans in Spain or laws that otherwise made fracking unviable. These regions include Cantabria (April 2013), La Rioja (May 2013), Catalonia (February 2014), Basque Country (June 2015), and Castillo La Mancha (March 2017).

In April 2017, Maryland became the third U.S. state to ban fracking when Governor Larry Hogan signed a ban bill that was overwhelmingly approved by the state legislature. Maryland's ban followed a two-and-a-half-year statewide moratorium.

Also in April 2017, Entre Ríos passed the first province-wide ban on fracking in Argentina. This ban follows 50 individual municipal bans and is intended to protect the Guarani Aquifer, which extends beneath parts of Argentina, Brazil, Paraguay, and Uruguay.

In June 2017, France expanded its fracking ban to include a ban on all new oil and gas exploration.

In July 2017, Ireland banned fracking when legislation was signed into law by the president.

Also in October 2017, Canada's Prince Edward Island included a prohibition on fracking as part of its Water Act.

According to campaigners, Albania enacted a national ban on fracking in 2017, but these reports remain unconfirmed by official sources.

In December 2017, Uruguay prohibited fracking for four years.

In March 2018, the Australian state of Tasmania extended its moratorium on fracking until 2025.

In November 2018, the Delaware River Basin Commission—which consists of governors from the four states of New York, New Jersey, Pennsylvania, and Delaware together with the U.S. Army Corps of Engineers—released a proposed rule to ban fracking in the Delaware River watershed on the grounds that fracking exposes its waters to “significant, immediate, and long-term risks.” As currently drafted, the rule provides for importation of wastewater from fracking

⁴⁰ Rogers, C. (2019, April 17). Supreme Court considers frac ban. *Winona Post*. Retrieved from <http://www.winonapost.com/Article/ArticleID/63818/Supreme-Court-considers-frac-ban>

operations located outside the Basin for storage, processing, and discharge within the Basin. It also provides for water withdrawals from the Delaware River and its tributaries for export and use in such operations.^{41, 42} The longest free-flowing river in the Northeast, the Delaware River provides drinking water to more than 15 million people (approximately five percent of the U.S. population). About one-third of the river system flows through shale formations. A de facto moratorium on fracking in the Delaware River Basin has been in place since 2010.

In December 2018, the newly elected president of Mexico announced a suspension of all further energy auctions for three years, temporarily halting permits for new fracking operations. This announcement is widely seen as a possible step by President Obrador toward fulfilling a campaign promise to ban fracking in Mexico.⁴³

On May 8, 2019, Washington State enacted a statewide ban on fracking.

On May 29, 2019, the Oregon Senate passed a five-year fracking moratorium. On June 17, Governor Kate Brown signed the bill into law.

In Connecticut, where no fracking or potential fracking takes place, ordinances prohibiting the storage or use of imported fracking waste have been passed in 56 municipalities. As we went to press in June 2019, the State House of Representatives, in a near-unanimous vote, passed a bill that enacts a permanent statewide ban on the disposal of oil and gas extraction waste, following a unanimous vote by the Connecticut Senate in May. The bill now goes to Governor Ned Lamont for signing.

Also, as we went to press, the New York State Senate voted for a bill that would end special exemptions from hazardous waste laws that allow fracking waste to be imported from out of state and dumped in municipal waste landfills and wastewater treatment plants. The bill now goes to the State Assembly for consideration. In spite of the statewide fracking ban, seven different landfills across New York State accept liquid and solid fracking waste from Pennsylvania. Seven New York county legislatures have banned that practice.

In sum, as evidence continues to mount of its environmental and public health costs, legislative and governmental bodies are increasingly apprehensive about the risks and harms of fracking.

Nevertheless, in several notable cases, hard-won bans and other restrictions on fracking have been overturned.

A fracking ban passed by the city of Denton, Texas in November 2014 was invalidated in June 2015 by a state law, pushed by the oil and gas industry, that prohibits Texas municipalities from passing local bans.

⁴² Hurdle, J. (2017, November 30). Fracking ban proposed for Delaware River basin; ‘significant risks’ cited. *StateImpact Pennsylvania*. Retrieved from <https://stateimpact.npr.org/pennsylvania/2017/11/30/fracking-ban-proposed-for-delaware-river-basin-significant-risks-cited/>

⁴³ Bertram, R. (2019, April 17). Will fracking be banned in Mexico? *Energy Transition*. Retrieved from

In June 2015, citing concerns about noise impacts and the industrialization of rural landscape, the county of Lancashire in northwest England halted plans for a major British fracking operation. Years previously, two wells—the first and only pair ever drilled in Lancashire—had suffered well integrity failures and caused earthquakes. However, in 2016, the national government overturned Lancashire’s ban, and drilling began in October 2017 despite widespread, ongoing public opposition.

In May 2016, the Colorado Supreme Court struck down local fracking bans in the cities of Fort Collins and Longmont. A statewide ballot measure to increase well setback distances in Colorado subsequently failed in November 2018. In January 2019, the Colorado Supreme Court ruled against a case brought by six youth that would have halted new drilling permits pending a comprehensive study of health and environmental impacts. The ruling allows Colorado to continue to weigh costs and technical feasibility against adverse public health impacts. However, in April 2019, the Colorado State legislature passed a bill that grants municipalities more regulatory authority over fracking activities.

In December 2017, Australia’s Northern Territory government delayed a decision on whether or not to extend or lift its own moratorium on fracking after a draft final report identified multiple risks to water, land, tourism, and indigenous culture. In April 2018, it lifted this moratorium.

In November 2018, the statewide moratorium in Western Australia was lifted over intense opposition, highlighting the limitations of aboriginal land rights. However, local bans in heavily populated areas of the state were left in place.

Introduction to Fracking

Since the end of the 20th century, horizontal drilling has been combined with high-volume hydraulic fracturing to create a novel approach to extracting dispersed oil and natural gas, primarily from shale bedrock, that would otherwise not flow to the surface. Typically, these unconventional extraction methods (collectively known as “fracking”) take place on clustered multi-well pads where individual wellbores extend vertically down into the shale formation and then turn horizontally, tunneling through the shale in various directions. These lateral tunnels can extend as far as two miles underground.

To liberate the gas (methane) or oil trapped inside the shale, many small explosive charges followed by high volumes of pressurized fluid are sent into the shale layer to expand and extend its many naturally occurring cracks, bedding planes, and faults. Silica sand grains (or sometimes ceramic beads) are carried by the pressurized fluid into these spaces and remain there after the pressure is released, acting to prop open these now-widened fissures in the shale and allowing the methane or oil trapped within to flow up the well.

Fracking fluid consists of millions of gallons of fresh water to which is added a sequence of chemicals that include biocides, lubricants, gelling agents, anti-scaling, and anti-corrosion agents. Some of the water used to frack wells remains trapped within the fractured zone and, as such, is permanently removed from the hydrologic cycle. The remainder travels back up to the surface. This flowback fluid contains not only the original chemical additives, many of which are toxic, but also harmful substances carried up from the shale zone, which often include brine, heavy metals, and radioactive elements.

Once in production, a fracked well continues to generate liquid throughout its lifetime. This produced water, which contains many of the same toxic substances as flowback fluid, is a second component of fracking waste, and it also requires containment and disposal. In addition, fracking waste includes solid drilling cuttings, which are typically laced with various chemical substances used to aid the drilling process. These cuttings, which can also contain radioactive elements, are typically disposed in municipal waste landfills. Fracking waste is exempt from federal hazardous waste regulations that would otherwise prohibit this practice.

Downstream elements of fracking infrastructure, which lie between the wellhead and the point of combustion, include processing plants, transport infrastructure such as pipelines and compressor stations, distribution lines storage facilities, gas-fired power plants, and LNG liquefaction plants and export terminals. Upstream elements include silica sand mining operations and water withdrawal operations.

As fracking operations in the United States have increased in frequency, size, and intensity, and as the transport of extracted materials has expanded, a significant body of evidence has emerged to demonstrate that these activities are dangerous to people and their communities in ways that are difficult—and may prove impossible—to mitigate. Risks include adverse impacts on water, air, agriculture, public health and safety, property values, climate stability, and economic vitality, as well as earthquakes.

Researching these complex, large-scale industrialized activities and the ancillary infrastructure that supports them takes time and has been hindered by institutional secrecy. Nonetheless, research is gradually catching up to the last decade's surge in fracking from shale. A growing body of peer-reviewed studies, accident reports, and investigative articles has detailed specific, quantifiable evidence of harm and has revealed fundamental problems with the entire life cycle of operations associated with unconventional drilling, fracking, and fracked-gas infrastructure. Industry studies, as well as independent analyses, indicate inherent engineering problems including uncontrolled and unpredictable fracturing, induced seismicity, extensive methane leakage, and well casing and cement failures that cannot be prevented with currently available materials and technologies.

Fracking-related problems also originate from sources independent of engineering. These include habitat destruction; inadequate solutions for wastewater disposal; the presence of abandoned wells or vertical fault lines that can serve as pathways for fluid migration into aquifers; and standard operational industry norms (venting, flaring, blowdowns) that contribute to methane releases and air pollution.

Earlier scientific predictions are now bolstered by extensive empirical data, confirming that the public health risks from unconventional gas and oil extraction are real, the range of adverse environmental impacts wide, and the negative economic consequences considerable. **Our examination of the peer-reviewed medical, public health, biological, earth sciences, and engineering literature uncovered no evidence that fracking can be practiced in a manner that does not threaten human health.**

Despite this expanding body of knowledge, industry secrecy continues to thwart scientific inquiry, leaving many potential problems—especially cumulative, long-term risks—unidentified, unmonitored, and largely unexplored. This problem is compounded by non-disclosure agreements, sealed court records, and legal settlements that prevent families and their doctors from discussing injuries and illnesses that result from fracking and frack-related operations. Consequently, no quantitative and comprehensive inventory of human hazards yet exists.

The long-entrenched problem of secrecy shows no sign of resolving. The identity of chemicals used in fracking fluids remains proprietary and lies beyond the reach of federal right-to-know legislation that governs other industries. The nation's largest public database on chemicals used in fracking operations, FracFocus, operates on a voluntary basis, and while 23 states have adopted it to serve as a *de facto* chemical disclosure registry, its data has, over time, become increasingly less, rather than more, comprehensive and transparent. As documented in a 2016 study by a Harvard University team, rates of withheld information and claims of trade secrecy have increased since FracFocus was first launched in 2011. (See footnotes 1445, 1446.)

The incomplete picture created by lack of transparency in regard to chemicals used, produced, emitted, or created during the drilling and fracking process complicates the task of identifying potential hazards and exposure pathways. Nevertheless, the evidence to date indicates that fracking operations pose severe threats to health, both from water contamination and from air pollution.

In the United States, more than two billion gallons of water and fracking fluids are injected daily under high pressure into the earth for the purpose of enabling oil and gas extraction via fracking

or, after the fracking is finished, to flush the extracted wastewater down any of the more than 187,000 disposal wells across the country that accept oil and gas waste. All of that two billion daily gallons of fluid is toxic, and the wells that ferry it pass through our nation's groundwater aquifers on their way to the deep geological strata below, where the injection of fracking waste demonstrably raises the risk for earthquakes.

In the air around drilling and fracking operations and their attendant infrastructure, researchers have measured strikingly high levels of toxic pollutants, including the potent carcinogen benzene and the chemical precursors of ground-level ozone (smog). In some cases, concentrations of fracking-related air pollutants in communities where people live and work exceed federal safety standards. Research shows that air emissions from fracking can drift and pollute the air hundreds of miles downwind. (See footnotes 182-184.)

About one-third of the natural gas inventory in the United States is used to generate electricity, and, enabled by fracking, natural gas has, as of 2016, exceeded coal as the nation's leading source of electricity.⁴⁴ With hydraulically fractured wells now producing 70 percent of U.S. natural gas and half of U.S. crude oil, and with hydraulic fracturing used in 95 percent of new wells, the "unconventional" techniques of fracking can no longer be considered atypical nor can the question of their public health risks be considered inconsequential.^{45, 46}

Drilling and fracking operations and their ancillary infrastructure have profoundly altered Earth's landscape. The flare stacks and artificial lights from major shale plays are visible from space,⁴⁷ as is the upward buckling of Earth's surface that is caused by the high-pressure injection of fracking wastewater into disposal wells.⁴⁸

The dramatic increase in fracking over the last decade in the United States has pushed oil and gas extraction operations into heavily populated areas. In the Marcellus Shale alone, which underlies much of the Mid-Atlantic United States, 15,939 wells were drilled and fracked between 2008 and 2018.⁴⁹ More than 11,000 of these wells are in Pennsylvania.

At least six percent of the U.S. population—17.6 million Americans—now live within a mile of an active oil or gas well, a number that includes 1.4 million young children and 1.1 million

elderly people.^{50, 51} About 8.6 million people are served by a drinking water source that is located within a mile from an unconventional well. (See footnote 302.) Understanding the potential for exposure and accompanying adverse impacts is a public health necessity.

Emerging Trends

1) Regulations are simply not capable of preventing harm.

Studies reveal inherent problems in the natural gas and oil extraction process, such as well integrity failures caused by aging or the pressures of fracking itself, and in the waste disposal process. These issues lead to water contamination, greenhouse gas emissions, air pollution with carcinogens and other toxic chemicals, earthquakes, and a range of environmental and other stressors inflicted on communities.

Some of fracking's many component parts—which include the subterranean geological landscape itself—are simply not controllable.

Compounding the innate unpredictability of the fracking process: The number of wells and their attendant infrastructure continue to proliferate, creating burgeoning cumulative impacts, and the size of individual wells keep growing. With the horizontal portions of a single well now extending as far as two miles or more underground, fluid injections, once typically three to five million gallons per fracked well, now can easily reach 10 to 20 million gallons per well.

The injection of ever-increasing volumes of fluids into an ever-increasing number of wells creates significant deformations in the shale. These are translated upwards, a mile or more, to the surface. Along the way, these “pressure bulbs” can impact, in unpredictable ways, faults and fissures in the overlying rock strata, including strata that intersect fresh water aquifers. Such pressure bulbs may mobilize contaminants left over from previous drilling and mining activities. (See footnotes 370, 371.) No set of regulations can obviate these potential impacts to groundwater.

No set of regulations can eliminate earthquake risks. (See footnote 752.) In spite of growing knowledge about the mechanics of how fracking and the underground disposal of fracking waste trigger earthquakes via activation of faults, no model can predict where or when earthquakes will occur or how powerful they will be. New research demonstrates that induced earthquakes can occur many miles from fracking sites. (See footnote 73.)

Regulations cannot prevent air pollution. The state of California determined that fracking can have “significant and unavoidable” impacts on air quality, including driving pollutants to levels that violate air quality standards. (See footnote 173.) In northeastern Colorado, ambient levels of atmospheric hydrocarbons have continued to increase even with stricter emission standards. (See

⁵⁰ Czolowski, E. D., Santoro, R. L., Srebotnjak, T., & Shonkoff, S. B. C. (2017). Toward consistent methodology to quantify populations in proximity to oil and gas development: A national spatial analysis and review. *Environmental Health Perspectives*, 125(8). doi: 10.1289/EHP1535

⁵¹ Konkel, L. (2017). In the neighborhood of 18 million: Estimating how many people live near oil and gas wells. *Environmental Health Perspectives*, 125(8). doi: 10.1289/EHP2553

footnote 188.) Tighter state regulations and tougher enforcement, including unannounced visits by state health inspectors equipped with infrared cameras, have reduced leaking methane and toxic vapors at individual well sites, but total air emissions continue to rise as the total number of wells continues to increase. At this writing, there are 53,000 active oil and gas wells in Colorado.⁵²

Leakage rates among active wells are wildly variable: Four percent of wells nationwide are responsible for fully half of all methane emissions from drilling and fracking-related activities. Predicting which wells will become “super-emitters” is not possible, according to a 2016 survey of 8,000 wells using helicopters and infrared cameras. Further, much of this leakage is engineered into the routine operation of fracking extraction, processing, and transport infrastructure, as when vapors are vented through release valves in order to regulate pressure. (See footnotes 994, 995.)

Long after they are decommissioned, well sites continue to leak in ways that are not always fixable. Abandoned wells are a significant source of methane leakage into the atmosphere, and, based on findings from New York and Pennsylvania, may exceed cumulative total leakage from oil and gas wells currently in production. Plugging abandoned wells does not always reduce methane emissions, and cement plugs themselves deteriorate over time. (See footnote 475.)

Further, countless abandoned wells are unmapped and their locations unknown. Many have no apparent owner. Across the nation, there are as many as three million abandoned wells. Pennsylvania alone is home to 200,000 to 750,000 abandoned wells, most of which are not charted or even visible on the surface.⁵³ No state or federal agency routinely monitors methane leakage from abandoned wells. (See footnotes 854, 859.) In Alberta, Canada, there are roughly 90,000 inactive wells in need of plugging, a number that is expected to double in the next eleven years. The Alberta Energy Regulator has estimated that the time required to plug and prepare 180,000 wells for clean-up and reclamation is 126 years. Another 77,000 wells in Alberta are plugged but not yet reclaimed.⁵⁴

2) Fracking and natural gas are incompatible with climate solutions.

On the grounds that natural gas emits, when combusted, only 53 percent of the carbon dioxide emitted by coal, early promoters of fracking argued that natural gas could serve as a “bridge fuel” while renewable energy sources ramp up. Scientific evidence now disproves these claims and shows that natural gas is as damaging to the climate as coal, and may be worse.

Natural gas is 85-95 percent methane, a short-lived but much more potent greenhouse gas than formerly appreciated. The Intergovernmental Panel on Climate Change estimates that, over a 20-

year time frame—longer than the dozen years remaining to limit global warming to 1.5° C—methane can, pound for pound, trap 86 times more heat than carbon dioxide. (See footnote 1045.)

Real-world methane leakage rates from drilling and fracking operations greatly exceed earlier estimates. Methane escapes into the atmosphere from all parts of the extraction, processing, and distribution system, all the way to the burner tip. In the heavily drilled Barnett Shale of northeastern Texas, methane emissions were shown to be 50 percent higher than the EPA had estimated. Fracking operations and associated infrastructure contributed 71-85 percent of the methane emissions in the region. A 2018 analysis of methane leaks from the U.S. oil and gas supply chain as a whole found leakage rates were 60 percent higher than reported by the EPA, and a 2019 study in southwestern Pennsylvania found shale gas emissions that were underreported by a factor of five when compared to EPA estimates. (See footnotes 944, 962.)

Much of the methane emitted from drilling and fracking activities and associated infrastructure originates not from accidental leaks but from purposeful losses that are inherent to the design of the industry's machinery or to normal operating use and are, therefore, not possible to mitigate. (See footnotes 1147-1149.) Methane is vented into the atmosphere during routine maintenance on compressor stations and pipelines; to create evaporative cooling for LNG storage and transport; during the flowback period after a well is fracked; and as an emergency procedure to control pressures. Inactive, abandoned wells are also significant methane emitters. Methane leakage at the levels now being documented, using multiple approaches in measurement and modeling, negates previously hypothesized benefits from burning methane instead of coal in most existing power plants.

Rising methane levels in the atmosphere make increasingly difficult the urgent task of limiting global warming to below levels called for in the Paris Agreement, which was based on older presumptions that global methane levels had plateaued. Instead, methane levels began to rise in 2007 and then shot up sharply in 2014.

At this writing, the cause of this ongoing methane surge is a subject of scientific debate. One hypothesis holds fossil fuel sources as the major driver. Another attributes the increase to biogenic sources, especially ruminant livestock. A third possibility is that rising global temperatures may be triggering methane release from wetlands, particularly in the southern tropics. Alternatively, the atmosphere's ability to break methane molecules apart may have become impaired, slowing the natural decay rate of methane.⁵⁵

The fossil fuel hypothesis is supported by a major 2017 study led by NASA researchers using satellite measurements and isotopic analysis that can distinguish methane produced by microbes from methane emissions arising from oil and gas extraction. (See footnote 963.) Building on this research in a forthcoming study, Cornell University earth systems scientist Robert Howarth used isotopic analysis to identify shale gas and oil extraction as the source of at least one-third of total

⁵⁵ Fletcher, S. E. M., & Shaefer, H. (2019). Rising methane: A new climate challenge. *Science*, 364(6444), 932-933. doi: 10.1126/science.aax1828

methane emissions, showing that the North American fracking boom is globally important in the current rise in global methane levels and “may well be the leading cause of the increased flux.”⁵⁶

Climate researcher Euan Nisbet, who has called for a renewed emphasis on reducing methane emissions to combat climate change, notes that, whatever the relative contribution of its various sources, fossil fuel extraction represents a powerful lever for intervention. “If the increased methane burden is driven by increased emissions from natural sources, and if this is a climate feedback—the warming feeding the warming—then there is urgency to reduce anthropogenic emissions, which we can control.” Reducing methane emissions from fossil fuels is the highest priority because they are relatively large and “thus offer attractive targets for rapid reduction, which are essential if the Paris Agreement aims are to be attained.” (see footnote 952.)

3) Fracking and the disposal of fracking waste threaten drinking water.

Cases of drinking water sources contaminated by drilling and fracking activities, or by associated waste disposal, are proven. Contamination occurs through three confirmed pathways: spills; discharge of fracking waste into rivers and streams; and underground migration of chemicals, including gas, into drinking water wells.

Methane and fracking-related contaminants can reach drinking water sources through cracks in well casings, through spaces between the casing and the wellbore, through naturally occurring fractures and fissures connecting shale layers with aquifers, and through abandoned wells. Methane migration into drinking water aquifers can change water chemistry in ways that mobilize metals or release hydrogen sulfide. (See footnote 248.)

Researchers working in Texas found 19 different fracking-related contaminants—including cancer-causing benzene—in hundreds of drinking water samples collected from the aquifer overlying the heavily drilled Barnett Shale, thereby documenting widespread water contamination. In Pennsylvania, a solvent used in fracking fluid was found in drinking water wells near drilling and fracking operations known to have well casing problems. In California, state regulators admitted that they had mistakenly allowed oil companies to inject drilling wastewater into aquifers containing clean, potable water. (See footnotes 352, 356, 360.) A 2017 study found that fracking wastewater discharged into rivers and streams through treatment plants created dozens of brominated and iodinated disinfection byproducts that are particularly toxic and “raise concerns regarding human health.” (See footnote 286.)

Fracking also threatens drinking water supplies through water depletion, especially in arid regions. According to a 2019 report, the volume of water used for fracking U.S. oil wells has more than doubled since 2016. (See footnote 245.) Oil and gas operations in the arid Permian Basin used eight times more water for fracking in 2018 as they did in 2011, threatening groundwater supplies. (See footnote 17.) In Arkansas, researchers found that water withdrawals for fracking operations deplete streams used for drinking water and recreation.

⁵⁶ Howarth, R. W. (2019). Is shale gas a major driver of recent increase in global atmospheric methane? *Biogeosciences*. Manuscript under review. doi: 10.5194/bg-2019-131

With increasing volumes of wastewater now exceeding the storage capacity for underground injection wells—and with underground injection linked to earthquake risk—Texas, Colorado, and New Mexico are now petitioning the EPA to allow release of fracking wastewater into rivers and streams and to allow its use for irrigation and watering livestock. These practices further imperil drinking water sources.⁵⁷

The trend toward mega-fracking, with longer and more extensive horizontal wellbores per well pad, coupled with the ongoing proliferation in the number of wells, has pushed the demand for water use in fracking operations ever higher, exacerbating both the problem of drinking water depletion and the problem of how to dispose of ever-increasing amounts of toxic fracking wastewater. A 2018 study found that water used for U.S. fracking operations increased by 770 percent per well between 2011 and 2016, while the amount of wastewater generated increased by 1,440 percent. (See footnote 259.)

As we went to press, a new study in Pennsylvania shows that, of the wastewater that remains in-state, 52 percent is reused in additional extraction operations, a practice that further concentrates chemical contaminants, including radioactive substances. The final destination for 35 percent of the total volume of liquid oil and gas waste generated in Pennsylvania from 1991-2017 is unknown because of gaps in reporting systems.⁵⁸

4) Drilling and fracking contribute to toxic air pollution and ground-level ozone at levels known to have health impacts.

More than 200 airborne chemical contaminants have been detected near drilling and fracking sites. Of these, 61 are classified as hazardous air pollutants, including carcinogens; 26 are endocrine-disrupting compounds that have been linked to reproductive, developmental, and neurological damage. (See footnotes 134, 146.) Drilling and fracking operations emit fine particles and vapors that combine to create ground-level ozone (smog). Exposure to these pollutants is known to cause premature death, exacerbate asthma, and contribute to poor birth outcomes and increased rates of hospitalization and emergency room visits.

Of the lower 48 states, six states (Texas, Oklahoma, Colorado, North Dakota, West Virginia, and Pennsylvania) produce nearly 70 percent of the nation's natural gas and over 74 percent of onshore crude oil. These six states experience the highest levels of ground-level ozone and fine particle pollution attributable to oil and gas extraction activities.

Volatile organic compounds (VOCs) from drilling and fracking operations, together with nitrogen oxides, are responsible for 17 percent of locally produced ozone in Colorado's heavily drilled Front Range. (See footnote 160.) Colorado has exceeded federal ozone limits for the past decade, a period that corresponds to a boom in oil and gas drilling (See footnote 158.) Air

⁵⁷ Lee, M. (2018, December 20). Oil patch states want authority for wastewater solutions. *E&E News*. Retrieved from <https://www.eenews.net/stories/1060110201>

⁵⁸ Hill, L. A. L., Czolowski, E. D., DiGiulio, D., & Shonkoff, S. B. C. (2019). Temporal and spatial trends of conventional and unconventional oil and gas waste management in Pennsylvania, 1991-2017. *Science of the Total Environment*, 674, 623-636. doi: 10.1016/j.scitotenv.2019.03.475

pollution near drilling and fracking operations is high enough in some Colorado communities to raise cancer risks, according to a 2018 study. (See footnote 145.)

Living near drilling and fracking operations significantly increases asthma attacks for residents of Pennsylvania. Those living near active gas wells are 1.5-4 times more likely to suffer from asthma attacks than those living farther away, with the closest group having the highest risk. (See footnotes 636, 637.)

In California, fracking occurs disproportionately in areas already suffering from serious air quality problems and can drive ozone and other federally regulated air pollutants to levels that violate air quality standards. (See footnotes 172, 173.) This increased air pollution and smog formation poses a serious risk to all those already suffering from respiratory issues, such as children with asthma. With an average of 203 high-ozone days a year, intensely fracked Kern County, California, is the fifth-most ozone-polluted county in the nation, according to the American Lung Association.

Several studies have documented a sharp uptick in atmospheric ethane, a gas that co-occurs with methane and whose presence is attributable to emissions from oil and gas wells. This trend reverses a previous, decades-long decline. Ethane is a potent precursor to ground-level ozone (See footnote 162-164.)

The United States leads the world in the number of drill site flaring operations. Flares are used to control pressure but, more frequently, to burn off natural gas as waste during oil drilling in places that lack infrastructure for gas capture and transport. The ongoing boom in domestic oil production enabled by fracking has caused natural gas flaring to proliferate. Emissions from flare stacks contribute to ozone creation and include several carcinogens, notably benzene and formaldehyde. Flaring also releases carbon monoxide, soot, and toxic heavy metals. In 2016, the EPA acknowledged that it had dramatically underestimated health-damaging air pollutants from flaring operations. (See footnotes 156, 157.) A 2017 study of plume samples from gas flares in North Dakota found that incomplete combustion from flaring is responsible for 20 percent of the total emissions of methane and ethane from the Bakken shale fields—more than double the expected value. (See footnote 152.) Results of a 2019 study of flaring in the Eagle Ford Shale region of Texas suggest that flaring may be a significant environmental exposure in counties where flare stacks are concentrated. (See footnote 137.)

5) Public health problems associated with drilling and fracking include poor birth outcomes, reproductive and respiratory impacts, and cancer risks.

Poor pregnancy outcomes and exacerbation of asthma have been linked to fracking activities in multiple studies in multiple locations using a variety of methodologies. (See footnote 1410.)

Studies of mothers living near oil and gas extraction operations consistently find impairments to infant health, including elevated risks for low birth weight and preterm birth. A 2017 study that examined birth certificates for all 1.1 million infants born in Pennsylvania between 2004-2013 found indicators of poorer infant health and significantly lower birth weights among babies born to mothers living near fracking sites. A 2015 Pennsylvania study found a 40 percent increase in the risk of preterm birth among infants born to mothers who lived nearby active drilling and

fracking sites, while a 2014 Colorado study found elevated incidence of neural tube defects and congenital heart defects. New studies in Texas and Colorado likewise found associations with infant deaths, high-risk pregnancies, and low birth weight. A 2017 pilot study in British Columbia found elevated levels of muconic acid—a marker of benzene exposure—in the urine of pregnant women living near fracking sites. (See footnotes 625, 627, 642, 664.)

As we went to press, a new pilot study reported elevated levels of barium and strontium in urine and hair samples of indigenous women living in an area of intense fracking activity in northeastern British Columbia. These trace metals, known to be released during hydraulic fracturing, are known developmental toxicants.⁵⁹

An emerging body of evidence, from both human and animal studies, shows harm to fertility and reproductive success from exposure to oil and gas operations, at least some of which may be linked to the dozens of known endocrine-disrupting chemicals used in hydraulic fracturing. (See footnotes 642, 1438, 1443, 1444.)

Other documented adverse health indicators among residents living near drilling and fracking operations variously include exacerbation of asthma as well as increased rates of hospitalization, ambulance runs, emergency room visits, self-reported respiratory problems and rashes, motor vehicle fatalities, trauma, drug abuse, and gonorrhea. Pennsylvania residents with the highest exposure to active fracked gas wells were nearly twice as likely to experience a combination of migraine headaches, chronic nasal and sinus symptoms, and severe fatigue. (See footnote 634.)

A 2017 Colorado study found higher rates of leukemia among children and young adults living in areas dense with oil and gas wells, while a Yale University research team reported that carcinogens involved in fracking operations had the potential to contaminate both air and water in nearby communities in ways that may increase the risk of childhood leukemia. The Yale team identified 55 known or possible carcinogens that are known to be used in fracking operations and that may be released into the air and water. Of these, 20 are linked to leukemia or lymphoma. (See footnotes 632, 1424.)

As we went to press, the *Pittsburgh Post-Gazette* documented 27 cases of Ewing’s sarcoma, a rare bone cancer that tends to strike young people, in four counties in southwestern Pennsylvania that are at the center of the Marcellus Shale fracking boom.⁶⁰ Six cases occurred in the same school district. (The typical rate is 250 cases of Ewing’s sarcoma per year in the United States as a whole. The cancer has no known cause.) There are also high numbers of other childhood cancers in the region, which is home to several polluting legacy industries. The Pennsylvania Department of Health reported “no conclusive findings” of a cancer cluster in the Canon-

McMillan School District and Washington County, but as additional cases have come to light, calls for more comprehensive investigations are ongoing.^{61, 62, 63, 64, 65}

6) Occupational health and safety risks for workers are severe and include both physical and chemical hazards.

Drilling and fracking operations are exempt from federal Occupational Safety and Health Administration (OSHA) standards designed to prevent catastrophic releases of toxic, flammable, or explosive chemicals in workplaces. They are also exempt from OSHA rules written for the construction industry designed to prevent falls and other accidents on the job. Although announced by the agency as forthcoming in 1983, federal safety regulations for the oil and gas industry have never materialized.^{66, 67} Instead, inspectors can only apply the “general duty clause” which is widely recognized as grossly inadequate for an industry with unique hazards and a fatality rate far above the national average. Fatality rate data for the oil and gas industry are limited, but available data in the seven years leading up to 2015 show fatality rates in oil and gas extraction that are four to seven times the national fatality rate. In 2017, the most recent year for which data are available, 81 oil and gas extraction workers died on the job, accounting for 72 percent of the fatal work injuries in the mining sector, which overall has a fatality rate nearly four times the national average.^{68, 69}

Studies in specific states, as well as some national studies, have provided additional details on regional rates and circumstances of injuries and deaths. Fatality rates among workers in the oil and gas extraction sector in North Dakota were seven times the national fatality rates in this industry, which itself has more deaths from fires and explosions than any other private industry.

An increase in workplace deaths likewise accompanied the initial fracking boom period in West Virginia.

Between 2011 and 2016, at least 60 workers at oil and gas drilling sites in Oklahoma were killed on the job. In January 2018, a natural gas rig exploded in southeastern Oklahoma, killing five workers when natural gas exploded during the drilling process. A “factual update” issued in August 2018 as part of an ongoing investigation by the U.S. Chemical Safety Board (CSB), determined that a piece of safety equipment was unable to fully close on the day of the accident and that other safety corners had been cut (See footnotes 532, 533, 537.) As we went to press, the CSB, released the final report on the accident, emphasizing that, in fact, two preventive barriers designed to prevent uncontrolled gas blowouts had failed as a consequence of significant lapses in safety protocols. Warning alarms did not sound. All five workers who died were trapped inside the driller’s cabin when fire blocked both exit doors. This problem, inherent to the design of the cabin, is not exceptional. The CSB investigation found that “there is no guidance to ensure that an emergency evacuation option is present onboard these rigs or can protect workers in the driller’s cabin from fire hazards.”^{70, 71}

Pipeline construction workers also suffer elevated rates of injuries and fatalities, dying on the job 3.5 times more than workers in other industries.

All together, according to a 2018 investigation, 1,566 U.S. workers in the oil and gas drilling industry died from on-the-job injuries in the decade between 2008 and 2017.

A University of Tennessee study assessed the occupational inhalation risks from the hazardous and carcinogenic air pollutants emitted from various sources around fracking wells and found that chemical storage tanks presented the highest cancer risk. Benzene has been detected in the urine of wellpad workers in Colorado and Wyoming. The National Institute for Occupational Safety and Health named oil and gas extraction industry workers among those at risk for silicosis, an incurable lung disease caused by exposure to silica dust, from the silica sand that is used extensively in fracking operations. (See footnotes 548, 586, 594.)

7) Earthquakes are a proven consequence of both fracking and the underground injection of fracking waste.

Injection of fracking wastewater into underground disposal wells is a known trigger of earthquake swarms in multiple locations, as demonstrated by several major studies, using different methodologies. Newer research in Canada, Oklahoma, and China links the practice of fracking itself to earthquakes, including some that take place many miles from well sites and

⁷¹ U.S. Chemical Safety and Hazard Investigation Board (2019, June 12). CBS issues final report into fatal gas well blowout [Press release]. Retrieved from <https://www.csb.gov/csb-issues-final-report-into-fatal-gas-well-blowout/>

many years later, suggesting that seismic risks have been previously underestimated with much larger areas at risk and for longer periods of time.^{72, 73}

A 2017 study of the Fort Worth Basin showed that a recent swarm of small earthquakes in northern Texas was originating in long-inactive fault lines in deep formations where fracking wastewater was being injected. Human activity is the only plausible explanation. (See footnote 499.) Another study using satellite-based radar imagery provided proof that the migration of fracking wastewater into faults increased pressures in ways that triggered a 4.8-magnitude earthquake in east Texas in 2012, while a third study documented the rupture of a fault plane that set off a 4.9-magnitude earthquake in Kansas in 2014 immediately following a rapid increase in fracking wastewater injection nearby. (See footnotes 747, 748.)

The number of earthquakes of magnitude 3.0 or higher skyrocketed in Oklahoma starting with the advent of the fracking boom—with fewer than two per year before 2009 and more than 900 in 2015. The 5.8 earthquake that struck near Pawnee on September 3, 2016 was the strongest in Oklahoma’s history and prompted an order from state regulators to shut down 67 wastewater disposal wells in the area. (See footnotes 745, 746.) In October 2016, the EPA recommended a moratorium on the underground injection of fracking wastewater in certain earthquake-prone parts of Oklahoma because regulations had not solved the problem. (See footnote 743.) Earthquake frequency began to decline in the state in 2017. In February 2018, after a new cluster of earthquakes, the state further restricted fracking activities.⁷⁴

There is no evidence that fracking-induced earthquakes can be prevented solely by limiting the rate or volume of injected fluid. A 2018 analysis of shale basins across the United States found that shallower disposal wells can help lower the risk of earthquakes. However, injection of fracking waste into shallow formations increases the risk of groundwater contamination. (See footnote 707.)

In China’s Sichuan Province, a series of recent earthquakes have been linked to fracking, including one in December 2018 with a magnitude of 5.7, the largest fracking-induced earthquake to date. The likely cause was reactivation of unmapped faults by underground fluid pressure.⁷⁵ In February 2019, three additional earthquakes, all with a magnitude of over four, struck Sichuan Basin, killing two people, injuring 13, and damaging 20,000 homes. The government temporarily suspended fracking operations in the area.⁷⁶

8) Fracking infrastructure poses serious potential exposure risks to those living nearby.

Drilling and fracking activities are relatively short-term operations, but compressor stations are semi-permanent facilities that pollute the air 24 hours a day as long as gas is flowing through pipelines. Day-to-day emissions from compressor stations are subject to highly episodic variations due to pressure changes and maintenance-related deliberate releases and can create periods of potentially extreme exposures. Compressor stations generally have shorter emissions stacks than other polluting facilities such as power plants, which means their harmful emissions are more concentrated at ground level than if released from a greater height. As we went to press, a new study of air emissions from 74 compressor stations in New York State found 39 chemicals known to be human carcinogens and documented large releases of greenhouse gases.⁷⁷

Because of their high pressures, compressor station explosions can have catastrophic consequences. On January 30, 2019, a compressor station in rural Michigan malfunctioned during a period of extreme cold and released a large amount of methane gas that ignited and exploded. On May 13, 2019, Boston-area physicians released a report detailing safety-related risks at a proposed natural gas compressor station in Weymouth, Massachusetts. In a worst case scenario explosion, injuries could extend for thousands of feet into densely populated residential neighborhoods, ignite an nearby industrial diesel fuel storage tank, and kill motorists driving on an adjacent highway.⁷⁸

Pipelines themselves can freeze, corrode, break, and leak. Low-pressure flow lines alone are responsible for more than 7,000 spills and leaks since 2009. (See footnote 1120.)

Significant pipeline accidents happen roughly 300 times each year in the United States and, between 1998 and 2017, killed 299 people and injured 1,190 others, according to the Pipeline and Hazardous Materials Safety Administration (PHMSA). In May 2019, PHMSA sent a warning to pipeline operators about increased risks of leaks and explosions caused by more frequent flooding, sinkholes, and severe rainfall patterns in the eastern United States.⁷⁹ In September 2018, heavy rains and landslides triggered the explosion of a pipeline in Beaver County, Pennsylvania, destroying a house.⁸⁰ All together, landslides have caused six pipeline explosions in the Appalachian region since early 2018.⁸¹

Gas-fired power plants are major emitters of carbon monoxide and nitrogen oxides, which contribute to smog.

In the Upper Midwest, Wisconsin residents living near silica sand mining operations that service the fracking industry reported dust exposure and respiratory problems. Silica dust is a known cause of silicosis and lung cancer. West Texas is also experiencing a fracking sand boom where roughly 20 new sand mines have opened since July 2017. (See footnote 17.)

Fracking infrastructure in the United States also includes 400 underground gas storage facilities in 31 states, with aging equipment and scant federal oversight. The four-month leak at the nation's fifth largest facility, Aliso Canyon in southern California, between October 2015 and February 2016 resulted in exposures of a large suburban population to an uncontrollable array of chemicals. With a release of nearly 100,000 metric tons of methane, it became the worst methane leak in U.S. history. (See footnote 1185.)

The Aliso Canyon blow-out exposed residents in the region to benzene spikes, high ongoing odorant releases, hydrogen sulfide at levels far above average urban levels, and many other contaminants of concern. More than 8,300 households were evacuated and relocated, with residents reporting multiple symptoms, including headaches, nosebleeds, eye irritation, and nausea. In May 2019, state investigators announced that the cause of the massive leak at Aliso Canyon was rupture of a well casing caused by microbial corrosion within a well that had been originally drilled in 1954. Over the years, the casing had come in contact with groundwater.⁸² The report also faulted the operator, SoCalGas, for failure to monitor and investigate more than 60 previous leaks at the gas storage complex.⁸³

In a 2018 analysis of the safety risks of all 14 facilities in California that store gas in depleted oil fields, the California Council of Science and Technology found that gas companies do not disclose the chemicals they are pumping underground nor do state regulators possess the necessary information to assess risks. Further, many wells servicing the storage fields are 60 to 90 years old with no regulatory limit to the age of the well. (See footnote 1178.)

LNG facilities—and the pipelines, coastal terminals, and ships that service them—are a rapidly growing component of fracking infrastructure as the shale gas boom has allowed the United States to seek long-term supply contracts for natural gas exports. In July 2017, the United Kingdom received its first delivery of LNG from the Sabine Pass export terminal in Louisiana. The Cove Point LNG export facility in Maryland sent its first shipments of Marcellus Shale gas, destined for Japan and India, in spring 2018. The United States is now a top international seller of natural gas with LNG exports expected to double by the end of 2019. At this writing, three LNG export terminals are in operation in the United States with another 22 in construction or approved for construction.^{84, 85}

LNG is purified methane in the form of a bubbling, super-cold liquid. It is created through the capital-intensive, energy-intensive process of cryogenics and relies on evaporative cooling to keep the methane chilled during transport. Explosive and with the ability to flash-freeze human flesh, LNG creates acute security and public safety risks. Its greenhouse gas emissions are 30 percent higher than conventional natural gas due to refrigeration, venting, leaks, and flaring, which is used to control pressure during regasification. The need to strip volatile impurities such as benzene from the gas prior to chilling it also makes LNG liquefaction plants a source of toxic air pollutants. (See footnotes 1226-1242.)

Cheniere Energy's Sabine Pass terminal in Louisiana became the subject of a federal investigation in January 2019 after a steel storage tank cracked and escaping LNG quickly vaporized into a flammable cloud. Another tank was found to be leaking gas from multiple places. PHMSA ordered both tanks shut down.⁸⁶

In May 2019, the state of Oregon denied a Clean Water Act permit for the proposed Jordan Cove LNG export terminal, and the fracked gas pipeline that would serve it, over concerns about likely harm to streams, estuaries, and wetlands. This infrastructure project cannot be built without the state permit, but the company has reapplied.⁸⁷

9) Drilling and fracking activities bring naturally occurring radioactive materials to the surface.

Naturally occurring radioactive materials that occur in shale layers containing oil and natural gas are brought to the surface in the solid waste removed during drilling (drill cuttings) and in fracking wastewater. Radionuclides can also build up in pipes and equipment, and fracking itself can open pathways for the migration of radioactive materials. Exposure to increased radiation levels from fracking materials is a risk for both workers and residents.

Radon levels in Pennsylvania homes have risen since the advent of the fracking boom, and buildings in heavily drilled areas have significantly higher radon readings than areas without well pads—a discrepancy that did not exist before 2004. (See footnote 511.) As we went to press, a new study reported a similar pattern in Ohio.⁸⁸

Also in Pennsylvania, a 2019 study measured levels of radium in drill cuttings that would exceed regulatory limits for disposal in landfills if drill cuttings were not exempt from federal regulations governing hazardous waste. Drill cuttings from Pennsylvania fracking operations are

routinely dumped in municipal waste landfills in Ohio and New York. (See footnote Swiedler, 2019.)

A variety of radioactive substances—including radium, thorium, and uranium—have been detected in fracking wastewater. A 2018 study in the Marcellus Shale region showed that extreme salinity, as well as the chemical composition of fracking fluid, interacts with the shale during the fracking process in ways that mobilize radium and make fracking wastewater radioactive. (See footnote 497.)

A 2018 simulation study of radium-226 in fracking wastewater from North Dakota’s Bakken Shale found potential risk to human health from fracking wastewater spills into surface water. (See footnote 500.)

10) Drilling and fracking activities harm wildlife through multiple pathways.

Animals serve as sentinels for chemical exposures that may also affect human residents who share their environment. In addition, animals perform ecosystem services essential to human existence, as confirmed by a landmark United Nations report in May 2019.⁸⁹ For both reasons, harm to wildlife by fracking operations has consequences for public health.

Birds and other wildlife have been poisoned by fracking wastewater held in open pits, while spills and discharges of fracking waste have precipitated mass die-offs of fish, as documented in Ohio, Kentucky, and Pennsylvania. (See footnotes 406, 434.) Freshwater mussels, which are endangered throughout North America, accumulate contaminants, including strontium, when fracking wastewater is discharged through sewage treatment plants. (See footnote 255.) Chemicals in fracking waste are toxic to, or otherwise disrupt development in, many fish and amphibian species. (See footnotes 246, 326.) In remote locations in Pennsylvania, streams once classified as high-quality brook trout habitat had no fish at all after the arrival of drilling and fracking operations. (See footnote 311.) Overall, aquatic habitats impacted by fracking activities show decreased biodiversity.

Wildlife is harmed by fracking through loss of food resources. Water fleas (*Daphnia spp.*), the basis of freshwater aquatic food chains, become unable to vertically navigate through water columns upon exposure to trace amounts of fracking fluid. (See footnote 241.) In West Virginia, populations of Louisiana Waterthrush, which rely on aquatic food sources, have declined in areas of drilling and fracking. (See footnote 247.)

Light and noise pollution from oil and gas production disrupt wildlife behavior, including in protected areas and critical habitats of endangered species, and have been linked to mass die-offs of waterfowl and declines in songbird populations in Alberta, Canada and New Mexico. (See footnotes 678, 693.) Chronic noise from drilling and fracking operations interferes with the ability of birds to respond to acoustic cues. (See footnotes 1111, 1112.)

Retrieved from https://www.ipbes.net/system/tdf/spm_global_unedited_advance.pdf?file=1&type=node&id=35245

Fracking harms wildlife through climate change and habitat destruction. Oil and gas infrastructure, including compressor stations, has caused declines in grassland songbirds in Canada. Sand mining operations in Texas are imperiling the dunes sagebrush lizard. The proposed route of the Atlantic Coast Pipeline cuts through critical habitat for four endangered species. A 2019 study found that forest disturbances driven by drilling and fracking activities are altering the abundance of songbird populations in central Appalachia, particularly harming species whose habitats are forest interiors.⁹⁰ Well pad construction hastens the spread of invasive non-native plant species which harms wildlife habitat. (See footnote 925.)

According to economists, the cost of wildlife habitat fragmentation due to fracking is \$3.5-4.45 billion. (See footnote 1276.)

11) The risks posed by fracking in California are unique.

Hydraulic fracturing in California is practiced differently than in other states, making its risks different as well. Wells are more likely to be vertical rather than horizontal, and the oil-containing rock layer is shallower. Hence, much less water is used per well for fracking as compared to other states. However, the fracking fluid used is much more chemically concentrated, the fracking zones are located closer to overlying aquifers, and the risk of a fracture reaching groundwater is higher.

California is the only state that allows wastewater from oil fields to be held in unlined open pits, which creates risks for both air and groundwater contamination. As of July 2018, 1,086 such pits were operational in the Central Valley, with the vast majority in Kern County. An investigation by reporters for NBC Bay Area found additional pits not on the state's official list. In at least two instances, toxic wastewater from the pits had migrated underground for more than a mile.⁹¹

In 2014, the discovery that companies had, for years, been wrongly allowed to inject fracking waste directly into California's freshwater aquifers led to the closing of 175 disposal wells. Impacts on drinking water are unknown. (See footnotes 289, 290.)

Most new fracking operations in California take place in areas with a long history of oil extraction. A high density of old and abandoned wells provides potential leakage pathways, should fractures intersect with them. And although fracking requires considerably less water per well in California, it takes place disproportionately in areas of severe water shortages and can compete with municipal and agricultural needs for freshwater.

The combination of ongoing drought and lack of disposal options has resulted in the diversion of fracking wastewater to farmers for irrigation of crops, raising concerns about contaminated water potentially affecting food crops and draining into groundwater. Investigative reports in 2015

⁹¹ Stock, S., Campos, R., Horn, M., & Ettema, K. (2018, July 31). Toxic wastewater from oil fields endangers California's water supply, scientists tell NBC Bay Area. *NBC Bay Area*. Retrieved from <https://www.nbcbayarea.com/investigations/Toxic-WasteWater-From-Oil-Fields-Endangers-Californias-Water-Supply-Scientists-Tell-NBC-Bay-Area-483089841.html>

revealed that Chevron Corporation piped 21 million gallons of recycled oil and gas wastewater per day to farmers for crop irrigation. Tests showed the presence of several volatile organic compounds, including acetone, which is linked in lab studies to kidney, liver, and nerve damage. (See footnotes 924-926.)

These activities project fracking's impacts onto geographically distant populations, especially in cases where wastewater is used in crop irrigation and livestock watering. Food is a troubling possible exposure route to fracking chemicals, in part because so little is known about these chemicals. According to a hazard assessment of chemicals used in California oil drilling operations that reuse wastewater for livestock watering and other agricultural purposes, more than one-third of the 173 chemicals used are classified as trade secrets: Their identities are entirely unknown. Of the remainder, ten are likely carcinogens, 22 are toxic air contaminants, and 14 had no toxicity data available. Estimating risks to consumers of the food produced with wastewater irrigation is thus not possible. (See footnote 919.)

The other area in California where fracking is concentrated, the Los Angeles Basin, is located directly under one of the most populous cities in the world. As of 2018, there were 3,468 active and 1,850 inactive oil and gas wells in Los Angeles County. (LA Dept of Health 2018). At least 1.7 million people in Los Angeles live or work within one mile of an active oil or gas well. California does not currently limit how close to residences or schools drilling and fracking activities may be conducted. A 2017 study shows that many of the same chemicals used to stimulate wells during fracking operations are also used in urban oil wells located in densely populated areas of southern California. (See footnote 295.)

12) Fracking in Florida presents many unknowns.

Gas and oil drilling in Florida, now only a minor industry, is currently concentrated in two areas: the western Panhandle near Pensacola and the Everglades area of southwest Florida. So far, fracking has been used at least once—in 2013 at a test well located in the Corkscrew Swamp Sanctuary near Naples in Collier County. The Texas company that fracked this well, using high-pressure acid fracturing techniques to dissolve the bedrock, received a cease and desist order from the Florida Department of Environmental Protection.⁹²

Renewed interest in oil and gas exploration in Florida has prompted public debate about fracking and whether to promulgate state regulations or prohibit it outright, possibly including a ban on the use of acid-dissolving technologies in addition to hydraulic fracturing *per se*. Bills that sought to ban fracking but not matrix acidizing failed to pass in the Florida legislature in the 2019 legislative session.⁹³

Florida has more available groundwater than any other state; it is the drinking water source for 93 percent of Florida's population. Groundwater is also pumped to irrigate crops and provide

⁹² Could leftover wastewater from balky oil well end up a health hazard? (2015, January 1). *Naples Daily News*. Retrieved from <http://archive.naplesnews.com/news/local/could-leftover-wastewater-from-balky-oil-well-end-up-a-health-hazard-ep-853723380-335781721.html/>

frost protection to winter crops. Most of this water is held in the Floridan Aquifer, which extends across the entire peninsula and into parts of Georgia, Alabama, and South Carolina. This aquifer provides drinking water to ten million people in both rural and urban communities, including residents of several major cities: Gainesville, Jacksonville, Orlando, Tallahassee, and Tampa. Overlain by smaller, shallower aquifers in southern Florida, it is a highly permeable, highly interconnected subterranean system, with water moving rapidly in multiple directions through massive shelves of limestone, which represent the dissolved shells and fossilized skeletons of prehistoric marine organisms. Honeycombed with pores, fissures, joints, and caves, the underground terrain of the Floridan Aquifer resembles a vast, brittle, sponge partly covered with sand and clay. Springs and sinkholes are common.^{94, 95}

It is not known whether fracking in Florida could induce sinkholes to open up or whether alterations in underground pressures could cause springs to go dry. Certainly, Florida's porous geology makes it vulnerable to groundwater contamination. Crumbly, soluble limestone offers pathways for contaminants spilled on the surface to travel deep into the aquifer, where they can be dispersed over great distances by the aquifer's river-like currents. A 2003 experiment with a dye tracer showed the special susceptibility of Florida's groundwater to potential contamination; within a few hours, the red dye traveled through the aquifer a distance (330 feet) that researchers had presumed would take days.⁹⁶

Compounding these risks, Florida's exposure to hurricanes makes it vulnerable to spills of fracking-related chemicals. In August 2017, flooding from Hurricane Harvey shut down fracking sites in Texas and triggered 31 separate spills at wells, storage tanks, and pipelines. (See footnotes 888-890.)

It is unclear where Florida would send any potential fracking wastewater for treatment and/or for underground injection. Florida currently injects other types of liquid waste into disposal wells that are located above, rather than below, oil- and gas-producing zones. The injection of fracking waste in these same shallower layers may make earthquakes less likely than, for example, in Oklahoma (where it is injected into deep formations), but it would also locate that waste closer to the aquifers, which are poorly mapped. To undertake the necessary study to determine how securely Florida's geological formations could contain wastewater from drilling and fracking operations and protect drinking water would be, in the words of two geophysicists, "a monumental task requiring full-time work...for decades."⁹⁷ There are reasons to be concerned. In

South Florida in the 1990s, 20 stringently regulated disposal wells failed and leaked sewage waste into the Upper Floridan Aquifer, a potential future source of drinking water for Miami.⁹⁸

13) The economic instabilities of fracking exacerbate public health risks.

Fracking is not a stable business. Although the fracking boom has lifted U.S. oil and gas production to all-time highs, shale wells drilled in the past five years are pumping significantly less oil and gas than their operators predicted to their investors. Because the production of individual shale wells falls precipitously over the course of a few years, operators must continue drilling new wells at an ever-swifter pace to maintain growth targets—even as owners are under pressure to cut costs in the face of price declines.

The result is lack of profits, dependency on Wall Street financing and low interest rates, and asset sell-offs throughout the fracking industry as a whole. (See footnote Olson, Wall St. J., Jan 2, 2019.) Between 2008 and 2018, leading fracking companies spent \$230 billion more than they earned, covering the gap with debt.⁹⁹

Even as oil prices have rebounded somewhat during the past two years, fracking companies are, collectively, still spending more on drilling than they receive by selling oil and gas. By 2018, only five of the largest 20 fracking companies were making more cash than they spent, and the stock prices of all 29 shale producers fell.^{100, 101}

These unstable economic fundamentals have multiple consequences for public health and safety as cumulative impacts mount from wells both old and new.

Pressures to cut costs incentivize cutbacks in safety measures and leave landscapes pock-marked by increasing numbers of hastily abandoned wells in need of remediation and long-term monitoring. Orphaned wells left behind by industry during energy price downturns or after bankruptcy are poorly monitored and, as conduits for gas and fluid leakage, become health and safety threats. Abandoned wells pose risks for soil and water contamination and can emit toxic air pollution and greenhouse gases. Some have exploded.^{102, 103, 104}

In both North Dakota's Bakken Shale and western Texas' Permian Basin, cost-cutting pressures, coupled with a desperate rush to drill new oil wells to compensate for declining rates of production from older wells, have meant that waste natural gas generated as a byproduct of oil drilling is simply vented or flared rather than captured, in order to speed up the rate of oil drilling.^{105, 106} By April 2019, the amount of natural gas burned off via flaring in the Permian oil fields had reached a record high and exceeded the amount of gas needed to power every residence in Texas.¹⁰⁷ Flaring, a leading source of toxic air pollution and smog, is a public health menace.¹⁰⁸

Independent economic analyses also show that the promise of local job creation has been greatly exaggerated, with many jobs going to out-of-area workers. Reports show that oil and gas jobs increasingly will be lost to automation.

With the arrival of drilling and fracking operations, communities have experienced steep increases in rates of crime including sex trafficking, rape, assault, drunk driving, drug abuse, and violent victimization—all of which carry public health consequences, especially for women. Social costs include road damage, failed local businesses, loss of affordable rental housing, and strains on law enforcement and municipal services. School districts report increased stress. Economic analyses have found that drilling and fracking activities threaten property values and can diminish tax revenues for local governments. Additionally, drilling and fracking on private lands pose an inherent conflict with mortgages and property insurance due to the hazardous materials used and the associated risks.

14) Fracking raises human rights and environmental justice issues.

Inequalities in opportunities to participate in environmental decision-making and uneven impacts of environmental hazards along racial and socioeconomic lines are signature issues of environmental justice. In multiple regions where fracking is practiced, well pads and associated infrastructure are disproportionately sited in non-white, indigenous, or low-income communities.^{109, 110}

A 2019 analysis of socio-demographic characteristics of people living close to drilling and fracking operations in the states of Colorado, Oklahoma, Pennsylvania, and Texas found strong evidence that minorities, especially African Americans, disproportionately live near fracking wells.¹¹¹

Similarly, a pattern of racially biased permitting was documented in the heavily fracked Eagle Ford area of southern Texas where a public health research team showed that disposal wells for fracking wastewater were more than twice as common in areas where residents are more than 80 percent people of color than in majority white communities.¹¹² Since 2007, more than 1,000 waste disposal wells have been permitted in the Eagle Ford Shale region where groundwater is the primary source of drinking water.¹¹³

In intensely drilled Denton, Texas, a study found that those benefiting most from Denton's mineral wealth tended to live elsewhere, while the environmental burdens remained local and fell hardest on those who did not have a voice in mineral-leasing decisions. "Non-mineral owners are essentially excluded from the private decisions, as the mineral owners not only receive the direct monetary benefits, but also hold a great deal of state-sanctioned power to decide if and how [shale gas development] proceeds."¹¹⁴

Poor communities of color are disproportionately affected by drilling activities in California. Of Los Angeles residents living within a quarter-mile of a well, more than 90 percent are people of color. In November 2015, civic groups led by youth sued the city of Los Angeles for racial discrimination based on allegations of a preferential permitting process and unequal regulatory enforcement for oil wells located in neighborhoods of color. Together, these differential practices have resulted in a higher concentration of wells with fewer environmental protections in Black and Latino communities.¹¹⁵ South Coast Air Quality Management District records show that oil drilling operations in Los Angeles neighborhoods released into the air 21 million pounds of toxic chemicals between June 2013 and February 2017. These emissions included crystalline silica, hydrofluoric acid, and formaldehyde.¹¹⁶

Across California, gas-fired power plants are disproportionately located in disadvantaged communities, as classified by an environmental justice screening tool developed by the state

Office of Environmental Health Hazard Assessment.¹¹⁷ More than three-quarters of the 21,397 new oil wells drilled in California between 2011 and 2018 are located in low-income minority communities, according to state data.¹¹⁸

In Greeley, Colorado, a massive well pad housing 24 wells was sited near Bella Romera Academy, an elementary school in a low-income community where 82 percent of students are Latino, after earlier plans were scrapped for a site near a charter school where students are majority white and middle-class.¹¹⁹

In May 2018, community groups in North Carolina filed an environmental justice complaint against the Atlantic Coast Pipeline, alleging the project poses disproportionate risk of harm to people of color. Thirteen percent of those living along the pipeline route are Native Americans in a state where Native Americans make up only 1.2 percent of the population.^{120, 121} A compressor station in Virginia that would service this pipeline is located in a historically African-American community.¹²²

In Pennsylvania, evidence shows that gas-fired power plants are disproportionately located in low-income and minority communities.¹²³ A geographic study found a higher concentration of drilling and fracking operations in impoverished communities throughout the state of Pennsylvania as well as in localized areas of West Virginia, but it did not find differences with respect to race. “The results demonstrate that the environmental injustice occurs in areas with unconventional wells in Pennsylvania with respect to the poor population.”¹²⁴ These findings are supported by census tract data in western Pennsylvania showing that among nearly 800 gas wells, only two were drilled in communities where home values exceeded \$200,000.¹²⁵

Similarly, in Ohio, geographic evidence reveals that disposal wells for fracking wastewater are

disproportionately located in lower-income, rural communities.¹²⁶

Apart from disparities circumscribed by race and income, fracking raises other fundamental questions of human rights. A comprehensive analysis that charts the international legal development of water rights as they apply to oil and gas extraction concluded that the right to water for residents living near fracking sites is “likely to be severely curtailed.” Noting that access to clean and safe drinking water is codified by the United Nations General Assembly as a human right essential to the full development of life and all other human rights, the authors argue that, because the fracking industry does not face the true societal cost of water in their production decisions, ownership of this essential-to-life resource is effectively transferred from society to industry, with no protection for this essential human right. In the United States alone, “there is considerable evidence that the human right to water will be seriously undermined by the growth of the unconventional oil and gas industry, and given its spread around the globe this could soon become a global human rights issue.”¹²⁷

Three international human rights bodies have called for prohibitions on fracking. In February 2019, the Committee on Elimination of Discrimination Against Women, which monitors the implementation of the 1979 United Nations treaty that serves as an international bill of rights for women, called on the United Kingdom to ban fracking on the ground that fracking damages communities and imperils the climate in ways that disproportionately harm women and girls living in rural areas.^{128, 129} In October 2018, the United Nations Committee on Economic, Social and Cultural Rights warned Argentina that its plans for large-scale fracking in the Vaca Muerta Shale region would create adverse economic and cultural rights impacts on the indigenous Mapuche people.¹³⁰ In May 2018, the Permanent People’s Tribunal, a Rome-based forum focused on human rights violations, issued an advisory opinion based on a two-year investigation that collected testimonies and reports from scientists and fracking-impacted communities.

In the words of the court,

The evidence clearly demonstrates that the processes of fracking contribute substantially to anthropogenic harm, including climate change and global warming, and involve massive violations of a range of substantive and procedural human rights and the rights of

nature. Thus the industry has failed to fulfill its legal and moral obligations.... The dangers of fracking to the rights of people, communities, and nature are inherent in the industry....We will go beyond the call for a moratorium and recommend that fracking should be banned.¹³¹

15) Health professionals are increasingly calling for bans or moratoria on fracking, based on a range of health hazards and as reviews of the data confirm evidence for harm.

In May 2015, the Medical Society of the State of New York passed a resolution recognizing the potential health impacts of natural gas infrastructure and pledging support for a governmental assessment of the health and environmental risks associated with natural gas pipelines. (See footnote 856.) The American Medical Association (AMA) adopted a similar resolution that supports legislation requiring all levels of government to seek a comprehensive Health Impact Assessment regarding the health and environmental risks associated with natural gas pipelines. (See footnote 855.)

In May 2016, Physicians for Social Responsibility called for a ban on fracking. (See footnote 1079.)

In July 2016, the UK health professional organization Medact released an updated assessment of the potential health impacts of shale fracking in England, concluding that the United Kingdom should abandon its policy to encourage shale gas extraction and urged an “indefinite moratorium” on fracking. (See footnote 1077.)

In October 2016, a group of health care professionals in Massachusetts called for an immediate moratorium on major new natural gas infrastructure until the impact of these projects on the health of the communities affected could be adequately determined through a comprehensive Health Impact Assessment. (See footnote 1074.) The group noted that the operation of natural gas facilities increases the risk of human exposures to toxic, cancer-causing, and radioactive pollution due to the presence of naturally co-occurring contaminants, toxic additives to the hydraulic fracturing process, and through the operation of transmission pipelines.

Also in 2016, in a unanimous vote of the society’s 300-member House of Delegates, the Pennsylvania Medical Society called for a moratorium on new shale gas drilling and fracking in Pennsylvania and an initiation of a health registry in communities with pre-existing operations. (See footnotes 1071, 1072).

In 2017, health officials in Los Angeles called for a comprehensive health study in the aftermath of the massive methane leak in Aliso Canyon. (See footnote 1068.)

In March 2019, Doctors for the Environment Australia announced the reinforcement of its position that no new gas extraction of any kind should occur in Australia.

Concerned Health Professionals of New York, which provided scientific and medical guidance for the successful effort to ban fracking in New York State, has inspired affiliations of like-minded public health scientists and health care providers that have been advocating for moratoria or bans on fracking in various other regions. These include Concerned Health Professionals of Maryland, Concerned Health Professionals of Ireland, Concerned Health Professionals of Neuquén, Argentina, and Concerned Health Professionals UK.

Conclusion

All together, findings to date from scientific, medical, and journalistic investigations combine to demonstrate that fracking poses significant threats to air, water, human health, public safety, community cohesion, long-term economic vitality, biodiversity, seismic stability, and climate stability.

The rapidly expanding body of scientific evidence compiled and referenced in the present volume is massive, troubling, and cries out for decisive action. Across a wide range of parameters, from air and water pollution to radioactivity to social disruption to greenhouse gas emissions, the data continue to reveal a plethora of recurring problems and harms that cannot be sufficiently averted through regulatory frameworks. There is no evidence that fracking can operate without threatening public health directly and without imperiling climate stability upon which public health depends. The only method of mitigating its grave harm to public health and the climate is a complete and comprehensive ban on fracking.

In the words of investigative journalist Andrew Nikiforuk:

Industry swore that its cracking rock technology was safe and proven, but science now tells a different story. Brute force combined with ignorance ... has authored thousands of earthquakes ... [and] called forth clouds of migrating methane.... The science is complicated but clear: cracking rock with fluids is a chaotic activity and no computer model can predict where those fractures will go. The regulatory record shows that they often go out of zone; extend into water; and rattle existing oil and gas wells, and these rattled wells are leaking more methane.¹³²

In closing, we cite comments by epidemiologist Irena Gorski, co-author of the 2019 review of fracking's health concerns published in the Oxford Research Encyclopedia of Global Public Health. Her words speak for all who have contributed to this Compendium:

What we found pushes back against the narrative we often hear that say we don't know enough about the health impacts yet. We have enough evidence at this point that these health impacts should be of serious concern to policymakers interested in protecting public health....As a fossil fuel, natural gas extraction and use is contributing to climate change, of course. But before conducting this study, I didn't realize the amount of evidence we have that it may be even worse than coal. We included this in our study because climate change has its own contributions to health impacts. These indirect impacts will take longer to appear than the direct health impacts, but they have the potential to be significant.¹³³

Compilation of Studies & Findings

Air pollution

Air pollution associated with fracking is a grave concern with a range of impacts. Researchers have documented more than 200 different air pollutants near drilling and fracking operations. Of these, 61 are classified as hazardous air pollutants with known health risks, and 26 are classified as endocrine disruptors. Areas with substantial drilling and fracking build-out show high levels of ground-level ozone (smog), striking declines in air quality, and, in several cases, increased rates of health problems with known links to air pollution. Air sampling surveys find high concentrations of volatile organic compounds (VOCs), especially carcinogenic benzene and formaldehyde, both at the wellhead and at distances that exceed legal setback distances from wellhead to residence. In some cases, VOC concentrations exceeded federal safety standards by several orders of magnitude. In 2018, researchers in Colorado documented that air pollution increased with proximity to drilling and fracking operations and was sufficiently high to raise cancer risks in some cases. Exposure to emissions from natural gas flares and diesel exhaust from the 4,000-6,000 truck trips per well pad also pose respiratory health risks for those living near drilling operations. The United States leads the world in the number of flare stacks. Air pollutants from flaring operations include VOCs, polycyclic aromatic hydrocarbons, carbon monoxide, toxic heavy metals, formaldehyde, and soot.

Evidence implicates the U.S. shale gas boom in the recent global spike in atmospheric ethane and propane. Drilling and fracking operations in North Dakota's Bakken oil and gas field alone contribute two percent of global ethane emissions and directly impact air quality across North America. Like methane, ethane is both a greenhouse gas and a precursor for ozone formation. The accelerating pace of drilling and fracking activities and the current policy plan to reverse course on proposed regulations to reduce methane emissions are likely to exacerbate the air pollution problems that fracking creates, along with attendant health risks.

- April 1, 2019 – A University of California, Berkeley team undertook a comprehensive review of current peer-reviewed literature on hazardous air pollutants found near oil and gas extraction operations. Hazardous air pollutants are those known or suspected to cause cancer, reproductive harm, birth defects, or other serious health effects. Reviewing 37 studies, the team identified a total of 61 different hazardous air pollutants that have been detected and measured near oil and gas drilling and fracking operations. The sources of these dangerous pollutants include a wide range of equipment, activities, and facilities—from dehydrators and condensate tanks to well drilling, flowback treatment, and oil storage facilities. The team found that the production phase of oil and gas extraction has the potential to emit the highest concentrations and the most complex mixtures of hazardous air pollutants over the longest time. (During the production phase, raw oil or natural gas is flowing from the well and is processed within various ancillary equipment, all of which can emit hazardous pollutants, such as benzene.) The highest and most sustained concentrations of hazardous air pollutants were found in “regions rich in oil,

wet gas, and condensate.” Their results further suggest that “exposure risks can be much higher if production equipment is collocated with condensate storage and wastewater impoundments.” The research team also uncovered an important disconnect between air pollution monitoring studies and those reporting on health impacts. In general, the levels of air pollution detected in the monitoring studies fell short of those known to cause health impacts and yet multiple health-based studies continue to find evidence of a spatial relationship between concentrations of hazardous air pollutants and incidence of health problems among people living near oil and gas operations. These findings suggest that existing air sampling methodologies may be under-reporting emissions or that prevailing health benchmarks are inadequate to identify health problems, especially when exposures include multiple chemicals.¹³⁴

- March 14, 2019 – Approximately 1.7 million people live within one mile of an active oil or gas well in the Los Angeles metropolitan area. A University of California pilot study investigated air pollution around active wells in this densely populated urban area and showed that, even in neighborhoods where residents are exposed to complex mixtures of air pollution from multiple sources, levels of several volatile organic pollutants are higher in communities closer to wellheads and decrease in concentration with distance away from the wellheads. These include the carcinogen benzene and n-hexane. “We were able to identify gradient behavior along the transect downwind of the target oil/natural gas facility that was likely due, in part, to emissions from the facility.”¹³⁵
- February 15, 2019 – In the first modeling study of drilling and fracking-related air pollution to include criteria air pollutants, a University of Texas, Arlington team found that concentrations of pollutants in the Barnett Shale region in north Texas were varied by terrain, with strongly sloping terrain giving the highest maximum concentrations for criteria air pollutants compared to level and moderate terrain. (Regulated by the U.S. Environmental Protection Agency [EPA] via applicable standards, the criteria air pollutants are ozone, particulate matter, lead, carbon monoxide, sulfur oxides, and nitrogen oxides.) The highest benzene and methane concentrations occurred in flat terrain and exceeded health-based standards.¹³⁶
- January 18, 2019 – Flaring is a widely used practice for disposal of waste natural gas during oil drilling, in places that lack infrastructure for its capture and transport. Enabled by fracking, domestic oil production is at an all-time high, and this upswing has outpaced the build-out of pipelines to contain the natural gas that accompanies the oil as it flows to the surface. Using satellite technology, researchers identified 43,887 distinct oil and gas

flares in the Eagle Ford Shale region of south Texas from 2012 to 2016, with a peak in activity in 2014 and an estimated 4.5 billion cubic meters of total gas volume flared over the study period. Comparing these results with well permit data showed the majority of flares (82 percent) were linked to oil wells, with more than 90 percent associated with horizontally drilled wells. These flares were not equally distributed across the region. Just five of 49 counties in the Eagle Ford Shale area accounted for 71 percent of flaring. “Our results suggest flaring may be a significant environmental exposure in parts of this region.” Air pollutants from flaring operations include VOCs, polycyclic aromatic hydrocarbons, carbon monoxide, toxic heavy metals, formaldehyde, and soot.¹³⁷

- July 27, 2018 – A report written by the United Kingdom’s Air Quality Expert Group found that shale gas operations would increase air pollution (nitrogen dioxides and VOCs) both nationally and locally within the United Kingdom. However, the report languished for three years and was finally released four days after shale gas extraction was officially approved for the Lancashire region of northwest England.^{138, 139}
- July 16, 2018 – A team from the Colorado Department of Public Health and Environment used existing air monitoring data sets from disparate locations to determine if air pollution levels near drilling and fracking operations are sufficient to create health problems in Colorado residents who live more than 500 feet away from a well head. Overall, they found individual VOC levels below those that are known to pose cancer and non-cancer health risks. However, the authors could not evaluate the risk of possible intermittent spikes in emissions during different phases of operation and evaluated only a subset of all VOCs emitted from drilling and fracking operations at these different phases. “Future studies are greatly needed that focus on quantifying these acute, peak exposures to people living near oil and gas operations, with particular emphasis on characterization of the volatile organic compounds identified as posing the greatest potential public health concerns, such as benzene.”¹⁴⁰
- July 13, 2018 – Drilling and fracking operations emit pollutants that form ozone and fine particles. Because air pollution from oil and gas operations originate from a large number of small, diffuse sources, estimating the level and location of emissions is difficult. An EPA team used a national emissions inventory for the year 2011 to characterize oil and gas emissions over space and time and to estimate the future human health burden

attributable to the oil and gas sector. For the year 2025, the authors projected that oil and gas extraction activities will cause 1000 deaths across the United States from exposure to fine particles and 970 deaths from ozone exposure, with the highest impacts in Colorado, Pennsylvania, Texas, and West Virginia.¹⁴¹

- June 13, 2018 – A British team used a new air quality forecasting model to simulate the health impacts of potential emissions from fracking operations in the United Kingdom, should large-scale fracking go forward. The results showed large projected increases in nitrogen oxides and volatile organic compounds across the UK airshed. These increases would contribute to approximately 110 extra premature deaths (with a range of 50-530 deaths) each year across the U.K.¹⁴²
- May 29, 2018 – An Oregon State University team measured polycyclic aromatic hydrocarbon air pollutants near drilling and fracking operations in rural eastern Ohio. A known component of fracking-related air pollution, polycyclic aromatic hydrocarbons are linked to cancer risk, respiratory distress, and poor birth outcomes. Using both air samplers and wristbands to assess personal exposures of residents living near active or proposed well sites, the researchers found elevated air pollution levels near active well sites. Further, the wristbands from participants who lived in homes with well pads on their property registered higher levels of air pollutants than participants without wells. “These findings suggest that living or working near an active natural gas extraction well may increase personal polycyclic aromatic hydrocarbon exposure.”¹⁴³
- May 18, 2018 – A Canadian and U.S. research team monitored methane levels in urban Morgantown, West Virginia during various stages of hydraulic fracturing at a single well pad. They found that emissions at the site were greatest during the flow-back stage, a result that supports previous studies.¹⁴⁴
- March 27, 2018 – A team led by University of Colorado School of Public Health scientists found that air pollution levels along Colorado’s heavily drilled Front Range increased with proximity to drilling and fracking operations and were sufficiently high to raise cancer risks. For people living within 500 feet of a well, lifetime cancer risks were eight times higher than the EPA’s upper threshold. Elevated levels of benzene and alkanes were of particular concern. “These findings indicate that state and federal

regulatory policies may not be protective of health for populations residing near oil and gas facilities.”¹⁴⁵

- March 21, 2018 – Evaluating 48 peer-reviewed studies that sampled air near drilling and fracking operations, researchers identified more than 200 different airborne chemicals associated with oil and gas extraction. Ethane, benzene, and n-pentane were the three most frequently detected. Twenty-six of these 200 chemicals are classified as endocrine disruptors—chemicals that can interfere with hormone systems and may affect reproduction, development, and neurological functioning.¹⁴⁶
- March 18, 2018 – There are now more than 22,000 active fracking wells in the rural Eagle Ford Shale region of Texas, which has undergone a 10-fold increase in oil and gas extraction since 2010. A research team from San Francisco State University and University of Southern California used remote sensing data that incorporated infrared observations of combustion sources to estimate exposure of local residents to hazardous air pollutants from associated flaring operations. Their method confirmed extensive flaring in close proximity to homes.¹⁴⁷
- February 26, 2018 – The presence of ethane and propane in the atmosphere is an indication of leaks during fossil fuel extraction and distribution, including fracking and its attendant activities, especially venting and flaring. (Fossil fuel combustion is not a source of ethane or propane.) According to a study led by a University of York team that used data collected from 20 observatories around the world, global atmospheric levels of ethane and propane have been underestimated by more than 50 percent. These results mean that hydrocarbon emissions from fossil fuel extraction activities in general—including methane—may be two to three times higher than previously presumed. Both ethane and methane are ozone precursors and contribute to the creation of smog. The authors noted that enhanced ethane and propane emission results mean higher levels of health-damaging ozone in both rural and urban areas.¹⁴⁸ In related press materials about this research, Ally Lewis, a co-author of the study, said, “Levels of ethane and propane declined in many places in the 1980s and 1990s, but global growth in the demand for natural gas means these trends may be reversing. The effects of higher ozone would be felt in the rural environment where it damages crops and plants, and in cities on human health.” Co-author Lucy Carpenter, said, “We know that a major source of ethane and propane in the atmosphere is from ‘fugitive’ or unintentional escaping emissions during

fossil fuel extraction and distribution. If ethane and propane are being released at greater rates than we thought, then we also need to carefully re-evaluate how much of the recent growth of methane in the atmosphere may also have come from oil and natural gas development.”¹⁴⁹

- February 5, 2018 – The Tropospheric Ozone Assessment Report analyzes data from all available ozone monitors around the world. Its 2018 report found that, in the United States, levels of ground-level ozone (smog) dropped steadily between 2000 and 2014 except in rural areas of the Rocky Mountain west where levels remained steady or rose. Oil and gas drilling is likely responsible. Rural areas in the western United States have fewer emission sources and yet they have been experiencing high ozone levels, especially in the winter.¹⁵⁰
- November 2, 2017 – In a review paper that explores how the U.S. fracking boom has contributed to air pollution in impacted communities, Texas A&M atmospheric scientist Gunnar W. Schade identified ozone and benzene as two important chemicals of concern. Documenting trends is challenging because fracking-related air pollutants typically originate in rural places without routine air pollution monitoring. A new air monitor in the Eagle Ford Shale region allowed researchers to use fingerprinting analysis to show that 60 percent of ambient benzene in the air now comes from drilling and fracking operations, including gas flares. Before the shale boom, the majority of benzene in the region came from tailpipe emissions. “In some areas, decades-long progress on ozone air quality has stalled; in others, particularly the Uintah basin in Utah, a new ozone problem has emerged due to the fracking industry’s emissions.” Downwind of the Eagle Ford Shale, San Antonio’s ozone levels are now trending close to 75 ppb, which exceeds the new recommended limit of 70 ppb. “The shale boom has create a new source of large-scale, diffuse hydrocarbon emissions that adversely affect air toxics levels. . . . The continued growth of the fracking industry as well as plans to remove regulations on methane emissions will not alleviate high hydrocarbon emissions and associated regional ozone problems.”¹⁵¹
- April 12, 2017 – Using aircraft, a University of Michigan-led team collected plume samples from 37 flare stacks in the Bakken Shale region of North Dakota to calculate emissions of black carbon (soot), methane, and ethane from natural gas flares. They

determined that flares contribute almost 20 percent of the total emissions of methane and ethane from the Bakken region, as measured by field studies.¹⁵²

- December 29, 2016 – Exposure to air pollutants from well pads decreases quickly with distance. However, according to recent studies, people living kilometers away from actual drilling and fracking operations also show elevated risk of disease known to be linked to air pollution. This review paper investigated the possible role that exposure to diesel exhaust from fracking-related road traffic is playing in creating public health impacts in surrounding communities. “Road traffic generated by hydraulic fracturing operations is one possible source of environmental impact whose significance has, until now, been largely neglected . . . with 4,000-6,000 vehicles visiting the well pad during the operations.” As a starting point for exposure assessment, the author recommended GIS modeling studies with a focus on traffic patterns and exacerbation of pediatric asthma.^{153, 154}
- October 16, 2016 – A review of recent studies documenting harm to both public health and agricultural yields from rising ozone levels identified oil and gas fields as “a major and growing source of ozone in the United States.”¹⁵⁵
- October 16, 2016 – In response to a lawsuit, the EPA acknowledged that its 33-year-old formula for estimating emissions from flaring operations requires revision as it may dramatically underestimate levels of health-damaging air pollutants. Emissions from flare stacks typically include carbon monoxide, nitrogen oxides, benzene, formaldehyde, and xylene, but levels of these smog-forming compounds are seldom measured directly.^{156, 157}
- October 5, 2016 – A review of recent studies documented connections between oil and gas development and worsening ozone levels in western states. Drilling and fracking operations have pushed Pinedale, Wyoming out of compliance with federal ozone standards. Colorado has exceeded federal ozone limits for the past decade, a period that corresponds to a statewide boom in oil and gas drilling.¹⁵⁸

- September 1, 2016 – A NASA-led research team collected whole air samples throughout the Barnett Shale basin in Texas. Chemical analysis showed that they contained benzene, hexane, and toluene at levels 2-50 times greater than the local background and similar to those seen in other intensely drilled shale basins in Colorado and Utah. There is “some evidence to suggest that public concerns for potential chronic health risks are not unwarranted.”¹⁵⁹
- July 23, 2016 – A study conducted at the Boulder Atmospheric Observatory examined sources of summertime ozone formation (smog) in Colorado’s Front Range and found that 17 percent of locally created ozone was created by VOCs from drilling and fracking operations.¹⁶⁰ Colorado has exceeded the federal ozone standard for the past nine years, a period of time that corresponds to a boom in oil and gas drilling in the Wattenberg Gas Field where the number of active wells has nearly doubled.¹⁶¹
- June 13, 2016 – Between 2009 and 2014, ethane emissions in the Northern Hemisphere increased by about 400,000 tons annually, the bulk of it from North American oil and gas activity, according to research by an international team led by the University of Colorado Boulder.¹⁶² After peaking in the 1970s, global ethane emissions began declining, primarily due to stricter air quality emission controls. In 2009, however, that downward trend reversed itself. “About 60 percent of the drop we saw in ethane levels over the past 40 years has already been made up in the past five years.... If this rate continues, we are on track to return to the maximum ethane levels we saw in the 1970s in only about three more years. We rarely see changes in atmospheric gases that quickly or dramatically,” said lead researcher Detlev Helmig.¹⁶³ Samples were collected from locations around the world, but the largest increases in ethane were documented over areas of heavy oil and gas activity in the central and eastern United States. Ethane contributes to the creation of ground-level ozone pollution (smog), a known human health hazard. The authors noted that “... ozone production from these emissions has led to air quality standard exceedances in the Uintah Basin, Utah, and Upper Green River Basin, Wyoming, [oil and natural gas] regions.” Two scientists not involved in the study published an accompanying commentary, concluding, “There is a danger that these non-methane hydrocarbon emission changes can offset emission policies and controls aimed at

reducing ozone concentrations,” and “[t]hese oil and gas operations are threatening to reverse what had been an important success story: decades of declining air pollution in North America.”¹⁶⁴ (See also the entry dated April 2, 2016 in Threats to the Climate System.)

- June 1, 2016 – Existing data on air pollutants emitted from drilling and fracking operations “support precautionary measures to protect the health of infants and children,” according to a review by a team of researchers (members of which include co-authors of this Compendium). Researchers focused on exposures to ozone, particulate matter, silica dust, benzene, and formaldehyde—all of which are associated with drilling and fracking operations—noting that all are linked to adverse respiratory health effects, particularly in infants and children. Benzene, for example, emitted from gas wells, production tanks, compressors, and pipelines, is a carcinogen also linked to serious respiratory outcomes in infants and children, including pulmonary infections in newborns. As the authors emphasized, this review did not consider other air pollutants commonly associated with drilling and fracking activities, namely hydrogen sulfide, polycyclic aromatic hydrocarbons, and oxides of nitrogen. Although improved exposure assessment, air monitoring, and long-term studies are still lacking, existing evidence was sufficient for the authors to “strongly recommend precautionary measures at this time.”¹⁶⁵
- April 26, 2016 – About two percent of global ethane emissions originate from the Bakken shale oil and gas field, which, according to research led by University of Michigan researchers, emits 250,000 tons of ethane per year.¹⁶⁶ “Two percent might not sound like a lot, but the emissions we observed in this single region are 10 to 100 times larger than reported in inventories. They directly impact air quality across North America. And they’re sufficient to explain much of the global shift in ethane concentrations,” according to Eric Kort, first author of the study.¹⁶⁷ Ethane is a gas that affects climate and decreases air quality. As a greenhouse gas, ethane is the third-largest contributor to human-caused climate change. Ethane contributes to ground-based ozone pollution as it breaks down and reacts with sunlight to create smog. This surface-level ozone is linked to respiratory problems, eye irritation, and crop damage. Global ethane levels were decreasing until 2009, leading the researchers to suspect that the U.S. shale gas boom may be responsible for the global increase in levels since 2010.
- April 5, 2016 – Helicopter-based infrared camera surveys of more than 8,000 oil and gas wells in seven U.S. regions found that well pads emit considerably more methane and VOCs than captured by earlier inventories. Moreover, these emissions were widely and

unpredictably variable from site to site and from well to well. Over 90 percent of total airborne emissions from well pads originated with vents and hatches on aboveground storage tanks.¹⁶⁸ The inability to predict which well sites were “superemitters” (meaning that they leaked into the air more than 200 cubic feet of methane and VOCs per hour) implies that continuous, site-specific monitoring is required to regulate methane leaks from drilling and fracking operations. In a comment about the findings to *InsideClimate News*, Cornell University engineer Anthony Ingraffea, who was not an author of the paper, said, “It makes regulation very difficult. If you have all these possible sites where you can have leaks, you can never have enough inspectors with all the right equipment being in all the right places at all the right times. It’s too complex a system.”¹⁶⁹

- February 19, 2016 – Legally enforced minimal distances between well sites and residences are based on political compromises rather than peer-reviewed science and “may not be sufficient to reduce potential threats to human health in areas where hydraulic fracturing occurs,” according to the findings of an interdisciplinary team including medical professionals and other researchers. The team incorporated geography, current regulations, historical records of blowout incidents and evacuations, thermal modeling, direct air pollution measurement, and vapor cloud modeling within the Marcellus (PA), Barnett (TX), and Niobrara (Northeastern and Northwestern Colorado and parts of Wyoming, Kansas, and Nebraska) Shale regions. The authors focused solely on well sites and excluded pipelines and compressor stations, which limited the data on explosions and evacuations and restricted air pollution results. Even so, the results showed that current natural gas well setbacks in the three areas “cannot be considered sufficient in all cases to protect public health and safety.” People living within setback distances are potentially vulnerable to thermal injury during a well blowout, and they are also susceptible to exposures of benzene and hydrogen sulfide at levels above those known to cause health risks.¹⁷⁰
- August 1, 2015 – “[C]linicians should be aware of the potential impact of fracking when evaluating their patients,” concluded a team writing on behalf of the Occupational and Environmental Health Network of the American College of Chest Physicians. Their article stated that the over 200,000 U.S. workers employed by well-servicing companies “... are exposed to silica, diesel exhaust, and VOCs, and, at some sites, hydrogen sulfide and radon, raising concerns about occupational lung diseases, including silicosis, asthma, and lung cancer.” The authors went on to say, “[i]n addition to occupational exposures, workers and nearby residents are also exposed to air pollutants emitted from various stages of fracking, including nitrogen oxides (NOx), VOCs, ozone, hazardous air pollutants, methane, and fine particulate matter.” Authors pointed to several recent

reversals in progress on air quality owed to fracking-related activity, including significant emissions of nitrogen oxides, a precursor of ozone, and spikes in fine particulate matter in fracking-intensive areas of Pennsylvania.¹⁷¹

- July 9, 2015 – The California Council on Science and Technology, in collaboration with the Lawrence Berkeley National Laboratory, released the second and third volumes of an extensive, peer-reviewed assessment of fracking in California. Air quality impacts are the focus of volume 2, chapter 3. The assessment found that current inventory methods underestimate methane and volatile organic chemical emissions from oil and gas operations and that fracking occurs in areas of California—most notably in the San Joaquin Valley and South Coast Air Basins—that already suffer from serious air quality problems. Further, no experimental studies of air emissions from drilling and fracking operations have ever been conducted in California. Although California has well-developed air quality inventory methods, they are “not designed to estimate well stimulation emissions directly, and it is not possible to determine well stimulation emissions from current inventory methods.”¹⁷²
- July 1, 2015 – In accordance with California Senate Bill No. 4, the California Division of Oil, Gas, and Geothermal Resources released a three-volume environmental impact report on oil and gas well stimulation treatments in the state (which, in California, include fracking along with acidizing and other unconventional extraction technologies that break up oil- or gas-containing rock). The Division determined that fracking and related operations can have “significant and unavoidable” impacts on air quality, including increasing ozone and other federally regulated pollutants to levels that violate air quality standards or that would make those violations worse.^{173, 174}
- May 29, 2015 – Each of stage of the drilling and fracking process “... has distinct operations that occur and particular sets of air emissions that may affect the respiratory tract,” wrote West Virginia University researcher Michael McCawley. Some states do have setback requirements, which “... may provide a margin of safety for fire and explosions but [do] not necessarily assure complete dilution or negligible exposure from air emissions.” His paper described the specific air contaminants associated with respiratory effects for each stage of operations. For example, the actual fracking stage potentially emits diesel exhaust, VOCs, particulate matter, ozone precursors, silica, and acid mists. McCawley reviewed the health effects linked to each of the contaminant types. Though many long-term effects may not yet be apparent in shale gas regions, “[a]t

a minimum, one would expect to see similar rates of respiratory disease to that found near highways with heavy traffic flow.”¹⁷⁵

- April 21, 2015 – In a study funded by the electric power industry, a research team found that fracking had diminished air quality in rural areas downwind of gas sites in two heavily drilled Pennsylvania counties but that concentrations of VOCs were not as high as expected based on results in other states. Methane levels were higher than previous research had found.¹⁷⁶ The extent to which the results can be generalized to the Marcellus basin as a whole, the authors emphasized, remains uncertain.¹⁷⁷
- April 15, 2015 – In a review of the literature, Colorado researchers demonstrated that four common chemical air pollutants from drilling and fracking operations—benzene, toluene, ethylbenzene, and xylene (BTEX)—are endocrine disruptors commonly found in ambient air that have the ability to interfere with human hormones at low exposure levels, including at concentrations well below EPA recommended exposure limits. Among the health conditions linked to ambient level exposures to the BTEX family of air pollutants: sperm abnormalities, reduced fetal growth, cardiovascular disease, respiratory dysfunction, and asthma.¹⁷⁸ “This review suggests that BTEX may...have endocrine disrupting properties at low concentrations, presenting an important line of inquiry for future research. BTEX are used globally in consumer products, and are released from motor vehicles and oil and natural gas operations that are increasingly in close proximity to homes, schools, and other places of human activity.”¹⁷⁹
- March 31, 2015 – University of Wyoming researchers identified a wastewater treatment and recycling facility as an important contributor to high winter ozone levels in Wyoming’s Green River Basin. The facility released a signature mixture of volatile hydrocarbons, including toluene and xylene, which are ozone precursors.¹⁸⁰ This study documented that recycling activities can transfer volatile pollutants from water into air when fracking wastewater is cleaned up for reuse and that water treatment emissions can serve as an important point source of air pollutants.¹⁸¹

- March 26, 2015 – Fracking can pollute air hundreds of miles downwind from the well pad, according to the results of a study from University of Maryland. Researchers took hourly measurements of ethane in the air over Maryland and the greater Washington, DC area, where fracking does not occur, and compared them to ethane data from areas of West Virginia, Pennsylvania, and Ohio where it does. They found month-to-month correlations, indicating that the ethane pollution in the air over Maryland appears to be coming from drilling and fracking operations in these other states. Ethane, a minor component of natural gas, rose 30 percent in the air over the Baltimore and Washington DC area since 2010, even as other air pollutants declined in concentration. By contrast, no increase in ethane levels were found in Atlanta, Georgia, which is not downwind of fracking operations.^{182, 183} Given this evidence for widespread ethane leakage, the paper’s lead author asked how much methane and other, more reactive emissions might be escaping from wells, noting that “a substantial amount of hydrocarbons” are emitted as a result of flowback procedures following the fracturing process.¹⁸⁴
- February 27, 2015 – A team of researchers from University of Texas, funded in part by the gas industry, examined ozone (smog) production resulting from natural gas extraction and use in Texas. Previous research by this team had found that the increased use of natural gas for generating electricity, as a replacement for coal, contributed to overall reductions in daily maximum ozone concentrations in northeastern Texas. By contrast, the results of this study found an increase in ozone in the Eagle Ford Shale area of south Texas. The Eagle Ford Shale is upwind from both Austin and San Antonio.¹⁸⁵ A potent greenhouse gas, methane is also a precursor for ground-level ozone and hence a contributor to smog formation.
- January 16, 2015 – Researchers from a number of universities, including the University of New Hampshire and Appalachian State University, used a source apportionment model to estimate the contribution of natural gas extraction activities to overall air pollution, including ozone, in heavily drilled southwest Pennsylvania. This regional air sampling effort demonstrated significant changes in atmospheric chemistry from drilling and fracking operations there. The researchers found that drilling and fracking operations may affect compliance with ozone standards.¹⁸⁶

- November 20, 2014 – The Texas Commission on Environmental Quality confirmed high levels of benzene emissions and other VOCs around an oil and gas facility in the Eagle Ford Shale. Symptoms reported by local residents were consistent with those known to be associated with exposure to such chemicals.¹⁸⁷
- November 14, 2014 – A University of Colorado at Boulder research team found that residential areas in intensely drilled northeastern Colorado have high levels of fracking-related air pollutants, including benzene. In some cases, concentrations exceed those found in large urban centers and are within the range of exposures known to be linked to chronic health effects. According to the study, “High ozone levels are a significant health concern, as are potential health impacts from chronic exposure to primary emissions of non-methane hydrocarbons (NMHC) for residents living near wells.” The study also noted that tighter regulations have not resulted in lower air pollution levels, “Even though the volume of emissions per well may be decreasing, the rapid and continuing increase in the number of wells may potentially negate any real improvements to the air quality situation.”¹⁸⁸
- October 30, 2014 – A research team assembled by University at Albany Institute for Health and the Environment identified eight highly toxic chemicals in air samples collected near fracking and associated infrastructure sites across five states: Arkansas, Colorado, Pennsylvania, Ohio, and Wyoming. The most common airborne chemicals detected included two proven human carcinogens (benzene and formaldehyde) and two potent neurotoxicants (hexane and hydrogen sulfide). In 29 out of 76 samples, concentrations far exceeded federal health and safety standards, sometimes by several orders of magnitude. Further, high levels of pollutants were detected at distances exceeding legal setback distances from wellheads to homes. Highly elevated levels of formaldehyde, for example, were found up to a half-mile from a wellhead. In Arkansas, seven air samples contained formaldehyde at levels up to 60 times the level known to raise the risk for cancer.¹⁸⁹ “This is a significant public health risk,” said lead author David O. Carpenter, MD, in an accompanying interview: “Cancer has a long latency, so you’re not seeing an elevation in cancer in these communities. But five, 10, 15 years from now, elevation in cancer is almost certain to happen.”¹⁹⁰
- October 21, 2014 – Responding to health concerns by local residents, a research team from University of Cincinnati and Oregon State University found high levels of air

pollution in heavily drilled areas of rural Carroll County, Ohio. Air monitors showed 32 different hydrocarbon-based air pollutants, including the carcinogens naphthalene and benzo[a]pyrene.¹⁹¹ The researchers plan additional monitoring and analysis.

- October 21, 2014 – Using a mobile laboratory designed by NOAA, a research team from the University of Colorado at Boulder, the NOAA Earth System Research Laboratory, and the Karlsruhe Institute of Technology looked at air pollution from drilling and fracking operations in Utah’s Uintah Basin. The researchers found that drilling and fracking emit prodigious amounts of volatile organic air pollutants, including benzene, toluene, and methane, all of which are precursors for ground-level ozone (smog). Multiple pieces of equipment on and off the well pad, including condensate tanks, compressors, dehydrators, and pumps, served as the sources of these emissions. This research shows that drilling and fracking activities are the cause of the extraordinarily high levels of winter smog in the remote Uintah basin—which regularly exceed air quality standards and rival that of downtown Los Angeles.¹⁹²
- October 2, 2014 – A joint investigation by *InsideClimate News* and the Center for Public Integrity found that toxic air emissions wafting from fracking waste pits in Texas are unmonitored and unregulated due to federal exemptions that classify oil and gas field waste as non-hazardous.¹⁹³
- October 1, 2014 – In a major paper published in *Nature*, an international team led by the National Oceanic and Atmospheric Administration demonstrated that exceptionally high emissions of VOCs explain how drilling and fracking operations in Utah’s Uintah Basin create extreme wintertime ozone events even in the absence of abundant ultraviolet light and water vapor, which are typically required to produce ground-level ozone (smog). Current air pollution trends in the United States are toward lower nitrogen oxides from urban sources and power generation, but increasing methane and VOCs from oil and gas extraction activities threaten to reverse decades of progress in attaining cleaner air. According to the study, the consequences for public health are “as yet unrecognized.”¹⁹⁴
- September 6, 2014 – As part of a comparative lifecycle analysis, a British team from the University of Manchester found that shale gas extracted via fracking in the United Kingdom would generate more smog than any other energy source evaluated (coal,

conventional and liquefied gas, nuclear, wind, and solar). Leakage of vaporous organic compounds during the necessary removal of hydrogen sulfide gas, along with the venting of gas both during drilling and during the process of making the well ready for production, were major contributors. “In comparison to other technologies, shale gas has high [photochemical smog]. In the central case, it is worse than solar PV, offshore wind and nuclear power by factors of 3, 26 and 45, respectively. Even in the best case, wind and nuclear power are still preferable (by factors of 3.3 and 5.6 respectively).”¹⁹⁵

- September 2014 – ShaleTest Environmental Testing conducted ambient air quality tests and gas-finder infrared video for several children’s play areas in North Texas that are located in close proximity to shale gas development. The results showed a large number of compounds detected above the Method Reporting Limit (the minimum quantity of the compound that can be confidently determined by the laboratory). Air sampling found three known/suspected carcinogens, and a number of other compounds associated with significant health effects. Benzene results from Denton, Dish, and Fort Worth are particularly alarming since they exceeded the long-term ambient air limits set by the Texas Commission on Environmental Quality, and benzene is a known carcinogen. “Benzene was found at all but one sampling location This is particularly noteworthy as benzene is a known carcinogen (based on evidence from studies in both people and lab animals), AND because it exceeds [levels above which effects have the potential to occur.]”¹⁹⁶
- August 24, 2014 – A *Salt Lake City Tribune* investigation found that evaporation from 14 fracking waste pits in western Colorado has added tons of toxic chemicals to Utah’s air in the last six years. Further, the company responsible operated with no permit, underreported its emissions and provided faulty data to regulators.¹⁹⁷
- August 2014 – A four-part investigation by the *San Antonio Express-News* found that natural gas flaring in the Eagle Ford Shale in 2012 contributed more than 15,000 tons of VOCs and other contaminants to the air of southern Texas—which is roughly equivalent to the pollution that would be released annually by six oil refineries. No state or federal agency is tracking the emissions from individual flares.¹⁹⁸
- June 26, 2014 – Public health professionals at the Southwest Pennsylvania Environmental Health Project reported significant recurrent spikes in the amount of particulate matter in the air inside of residential homes located near drilling and fracking operations. Captured by indoor air monitors, the spikes tend to occur at night when stable atmospheric conditions hold particulate matter low to the ground. Director Raina Ripple emphasized

that spikes in airborne particulate matter are likely to cause acute health impacts in community members. She added, “What the long-term effects are going to be, we’re not certain.”¹⁹⁹

- May 8, 2014 – Researchers at NOAA found high levels of methane leaks as well as benzene and smog-forming VOCs in the air over oil and gas drilling areas in Colorado. Researchers found methane emissions three times higher than previously estimated and benzene and VOC levels seven times higher than estimated by government agencies. The *Denver Post* noted that Colorado’s Front Range has failed to meet federal ozone air quality standards for years.²⁰⁰
- April 26, 2014 – A Texas jury awarded a family \$2.8 million because, according to the lawsuit, a fracking company operating on property nearby had “created a ‘private nuisance’ by producing harmful air pollution and exposing [members of the affected family] to harmful emissions of volatile organic compounds, toxic air pollutants and diesel exhaust.” The family’s 11-year-old daughter became ill, and family members suffered a range of symptoms, including “nosebleeds, vision problems, nausea, rashes, blood pressure issues.”²⁰¹ Because drilling did not occur on their property, the family had initially been unaware that their symptoms were caused by activities around them.
- April 16, 2014 – Reviewing the peer-review literature to date of “direct pertinence to the environmental public health and environmental exposure pathways,” a U.S. team of researchers concluded: “[a] number of studies suggest that shale gas development contributes to levels of ambient air concentrations known to be associated with increased risk of morbidity and mortality.”²⁰²
- April 11, 2014 – A modeling study commissioned by the state of Texas made striking projections about worsening air quality in the Eagle Ford Shale. Findings included the possibility of a 281 percent increase in emissions of VOCs. Some VOCs cause respiratory and neurological problems; others, like benzene, are also carcinogens. Another finding was that nitrogen oxides—which react with VOCs in sunlight to create ground-level ozone, the main component of smog—increased 69 percent during the peak ozone season.²⁰³
- March 29, 2014 – Scientists warn that current methods of collecting and analyzing emissions data do not accurately assess health risks. Researchers with the Southwest

Pennsylvania Environmental Health Project showed that methods do not adequately measure the intensity, frequency, or durations of community exposure to the toxic chemicals routinely released from drilling and fracking activities. They found that exposures may be underestimated by an order of magnitude, mixtures of chemicals are not taken into account, and local weather conditions and vulnerable populations are ignored.²⁰⁴

- March 27, 2014 – University of Texas research pointed to “potentially false assurances” in response to community health concerns in shale gas development areas. Dramatic shortcomings in air pollution monitoring to date include no accounting for cumulative toxic emissions or children’s exposures during critical developmental stages, and the potential interactive effects of mixtures of chemicals. Chemical mixtures of concern include benzene, toluene, ethylbenzene, and xylenes.^{205, 206}
- March 13, 2014 – VOCs emitted in Utah’s heavily drilled Uintah Basin led to 39 winter days exceeding the EPA’s eight-hour National Ambient Air Quality Standards level for ozone pollutants the previous winter. “Levels above this threshold are considered to be harmful to human health, and high levels of ozone are known to cause respiratory distress and be responsible for an estimated 5,000 premature deaths in the U.S. per year,” according to researchers at the University of Colorado. Their observations “reveal a strong causal link between oil and gas emissions, accumulation of air toxics, and significant production of ozone in the atmospheric surface layer.”²⁰⁷ Researchers estimated that total annual VOC emissions at the fracking sites are equivalent to those of about 100 million cars.²⁰⁸
- March 3, 2014 – In a report summarizing “the current understanding of local and regional air quality impacts of natural gas extraction, production, and use,” a group of researchers from NOAA, Stanford, Duke, and other institutions described what is known and unknown with regard to air emissions including greenhouse gases, ozone precursors (VOCs and nitrogen oxides), air toxics, and particulates. Crystalline silica was also discussed, including as a concern for people living near well pads and production staging areas.²⁰⁹

- February 18, 2014 – An eight-month investigation by the *Weather Channel*, the *Center for Public Integrity*, and *InsideClimate News* into fracking in the Eagle Ford Shale in Texas revealed that fracking is “releasing a toxic soup of chemicals into the air.” They noted very poor monitoring by the state of Texas and reported on hundreds of air complaints filed relating to air pollution associated with fracking.²¹⁰
- December 18, 2013 – An interdisciplinary group of researchers in Texas collected air samples in residential areas near shale gas extraction and production, going beyond previous Barnett Shale studies by including emissions from the whole range of production equipment. They found that most areas had “atmospheric methane concentrations considerably higher than reported urban background concentrations,” and many toxic chemicals were “strongly associated” with compressor stations.²¹¹
- December 10, 2013 – Health department testing at fracking sites in West Virginia revealed dangerous levels of benzene in the air. Wheeling-Ohio County Health Department Administrator Howard Gamble stated, “The levels of benzene really pop out. The amounts they were seeing were at levels of concern. The concerns of the public are validated.”²¹²
- October 11, 2013 – Air sampling before, during, and after drilling and fracking of a new natural gas well pad in rural western Colorado documented the presence of the toxic solvent methylene chloride, along with several polycyclic aromatic hydrocarbons at “concentrations greater than those at which prenatally exposed children in urban studies had lower developmental and IQ scores.”²¹³
- September 19, 2013 – In Texas, air monitoring data in the Eagle Ford Shale area revealed potentially dangerous exposures of nearby residents to hazardous air pollutants, including cancer-causing benzene and the neurological toxicant, hydrogen sulfide.²¹⁴
- September 13, 2013 – A study by researchers at the University of California at Irvine found dangerous levels of VOCs in Canada’s “Industrial Heartland” where there are more than 40 oil, gas, and chemical facilities. The researchers noted high levels of

hematopoietic cancers (leukemia and non-Hodgkin's lymphoma) in men who live closer to the facilities.²¹⁵

- April 29, 2013 – Using American Lung Association data, researchers with the Environmental Defense Fund determined that air quality in rural areas with fracking was worse than air quality in urban areas.²¹⁶
- March 2013 – A review of regional air quality damages in parts of Pennsylvania in 2012 from Marcellus Shale development found that air pollution was a significant concern, with regional damages ranging from \$7.2-\$32 million in 2011.²¹⁷
- February 27, 2013 – In a letter from Concerned Health Professionals of New York to Governor Andrew Cuomo, a coalition of hundreds of health organizations, scientists, medical experts, elected officials, and environmental organizations noted serious health concerns about the prospects of fracking in New York State, making specific note of air pollution.²¹⁸ Signatory organizations included the American Academy of Pediatrics of New York, the American Lung Association of New York, and Physicians for Social Responsibility. The New York State Medical Society, representing 30,000 medical professionals, has issued similar statements.²¹⁹
- January 2, 2013 – A NOAA study identified emissions from oil and gas fields in Utah as a significant source of pollutants that contribute to ozone problems.²²⁰ Exposure to elevated levels of ground-level ozone is known to worsen asthma and has been linked to respiratory illnesses and increased risk of stroke and heart attack.²²¹
- December 3, 2012 – A study linked a single well pad in Colorado to more than 50 airborne chemicals, 44 of which have known health effects.²²²

- July 18, 2012 – A study by the Houston Advanced Research Center modeled ozone formation from a natural gas processing facility using accepted emissions estimates and showed that regular operations could significantly raise levels of ground-level ozone (smog) in the Barnett Shale in Texas and that gas flaring further contributed to ozone levels.²²³
- March 19, 2012 – A Colorado School of Public Health study found air pollutants near fracking sites linked to neurological and respiratory problems and cancer.^{224, 225} The study, based on three years of monitoring at Colorado sites, found a number of “potentially toxic petroleum hydrocarbons in the air near gas wells including benzene, ethylbenzene, toluene, and xylene.” Lisa McKenzie, PhD, MPH, lead author of the study and research associate at the Colorado School of Public Health, said, “Our data show that it is important to include air pollution in the national dialogue on natural gas development that has focused largely on water exposures to hydraulic fracturing.”²²⁶
- December 12, 2011 – Cancer specialists, cancer advocacy organizations, and health organizations summarized the cancer risks posed by all stages of the shale gas extraction process in a letter to New York Governor Andrew Cuomo.²²⁷
- October 5, 2011 – More than 250 medical experts and health organizations reviewed the multiple health risks from fracking in a letter sent to New York Governor Andrew Cuomo.²²⁸
- April 21, 2011 – *Environment & Energy (E&E)* reported that ozone levels exceeding federal health standards in Utah’s Uintah Basin, as well as wintertime ozone problems in other parts of the Intermountain West, stem from oil and gas extraction. Levels reached nearly twice the federal standard, potentially dangerous even for healthy adults to breathe. Keith Guille, spokesman for the Wyoming Department of Environmental Quality, said, “We recognize that definitely the main contributor to the emissions that are out there is the oil and gas industry....”²²⁹

- March 8, 2011 – The Associated Press reported that gas drilling in some remote areas of Wyoming caused a decline of air quality from pristine mountain air to levels of smog and pollution worse than Los Angeles on its worst days, resulting in residents complaining of watery eyes, shortness of breath, and bloody noses.²³⁰
- November 18, 2010 – A study of air quality in the Haynesville Shale region of east Texas, northern Louisiana, and southwestern Arkansas found that shale oil and gas extraction activities contributed significantly to ground-level ozone (smog) via high emissions of ozone precursors, including VOCs and nitrogen oxides.²³¹ Ozone is a key risk factor for asthma and other respiratory and cardiovascular illnesses.^{232, 233, 234, 235}
- September 2010 – A health assessment by the Colorado School of Public Health for gas development in Garfield County, Colorado determined that air pollution will likely “be high enough to cause short-term and long-term disease, especially for residents living near gas wells. Health effects may include respiratory disease, neurological problems, birth defects and cancer.”^{236, 237}
- January 27, 2010 – Of 94 drilling sites tested for benzene in air over the Barnett Shale, the Texas Commission on Environmental Quality discovered two well sites emitting what they determined to be “extremely high levels” and another 19 emitting elevated levels.²³⁸

Water contamination

Substantial evidence shows that drilling and fracking activities, and associated wastewater disposal practices, inherently threaten groundwater and have polluted drinking water sources. Repudiating industry claims of risk-free fracking, studies from across the United States present irrefutable evidence that groundwater contamination occurs as a result of fracking activities and is more likely to occur close to well pads. In Pennsylvania alone, the state has determined that 343 private drinking water wells have been contaminated or otherwise impacted as the result of drilling and fracking operations over an eight-year period. As determined by the U.S. Agency for Toxic Substances and Disease Registry (ATSDR), the chemical contamination of some private water wells in Dimock, Pennsylvania posed demonstrable health risks, rendering the water unsuitable for drinking.

Evidence of instances and pathways of water contamination exist even though scientific inquiry is impeded by industry secrecy and regulatory exemptions. The 2005 Energy Policy Act exempts hydraulic fracturing from key provisions of the Safe Drinking Water Act. As a result, fracking chemicals have been protected from public scrutiny as “trade secrets.” The oil and gas sector is the only U.S. industry permitted to inject known hazardous materials near, or directly into, underground drinking water aquifers. At the same time, in most states where fracking occurs, routine monitoring of groundwater aquifers near drilling and fracking operations is not required, nor are companies compelled to fully disclose the identity of chemicals used in fracking fluid, their quantities, or their fate once injected underground.

Nevertheless, of the more than 1,000 chemicals that are confirmed ingredients in fracking fluid, an estimated 100 are known endocrine disruptors, acting as reproductive and developmental toxicants. Adding to this mix are heavy metals, radioactive elements, brine, and volatile organic compounds (VOCs), which occur naturally in deep geological formations and which can be carried up from the fracking zone with the flowback fluid. As components of the fracking waste stream, these toxic substances also pose threats to surface water and groundwater. A 2017 study found that spills of fracking fluids and fracking wastewater are common, documenting 6,678 significant spills occurring over a period of nine years in four states alone. In these states, between 2 and 16 percent of wells report spills each year. About five percent of all fracking waste is lost to spills, often during transport.

Spills and intentional discharges of fracking waste into surface water have profoundly altered the chemistry and ecology of streams throughout entire watersheds, increasing downstream levels of radioactive elements, heavy metals, endocrine disruptors, toxic disinfection byproducts, and acidity, and decreasing aquatic biodiversity and populations of zooplankton and sensitive fish species, such as brook trout. Recent studies documenting changes in the bacterial flora in groundwater following drilling and fracking operations represent an emerging area of concern.

Demand for water to use in U.S. fracking operations continues to rise and has more than doubled since 2016. Unlike water used for agriculture or other industrial uses, the water used for fracking that remains in the shale bedrock is permanently lost to the hydrologic cycle. A suite of new studies now show that fracking can deplete streams and aquifers in ways that contribute to water stress and water scarcity. A 2018 study found that water use for fracking

operations increased by 770 percent per well between 2011 and 2016 across all U.S. shale basins. At the same time, the volume of fracking wastewater generated during the first year of extraction increased by up to 1440 percent. There is no known solution for the problem of fracking wastewater. It cannot be filtered to create clean, drinkable water, nor is there any safe method of disposal. Recycling is an expensive, limited option that increases radionuclide levels of subsequent wastewater. Underground reservoirs that receive fracking wastewater via injection into disposal wells, a practice that is linked to earthquakes, are reaching capacity in many regions of the United States.

- March 28, 2019 – Chemical surfactants are added to fracking fluid to emulsify, reduce surface tension, and inhibit corrosion. An engineering team looked at the chemical fate of these additives when they come back to the surface as shale gas wastewater. They found that high dissolved solids (salts) in the wastewater inhibit microbes that assist in biodegradation. “The presence of higher total dissolved solids appeared to exert an appreciable, long-standing effect on microbial community composition within one week of exposure to increased salinity, suggesting that an accidental release of recycled produced water may upset naturally occurring microbial communities.” These results imply that accidental spills of shale gas wastewater—or deliberate releases (as when fracking wastewater is used for de-icing roads or irrigation)—are likely to result in the environmental persistence of these surfactant chemicals. These findings have implications for treating and recycling fracking wastewater. Its high salt levels mean that it must be filtered through special desalinating membranes, but the persistent presence of surfactant chemicals can clog and damage these membranes.²³⁹
- March 14, 2019 – Rainbow trout exposed to levels of fracking wastewater that mimic those that would result from a low-level spill, as from a pipeline leak into a small river, did not show significant signs of salinity stress. However, their blood plasma did accumulate strontium and bromide. This study did not examine possible endocrine disrupting effects.²⁴⁰
- March 5, 2019 – Water fleas (*Daphnia spp.*) are freshwater zooplankton that feed on phytoplankton and play a crucial role in aquatic food webs. In a Canadian study, water fleas exposed to various concentrations of fracking wastewater displayed altered behaviors that impaired their ability to orient toward light, a response that allows them to avoid predation and find food. This study helps explain the results of earlier research that links fracking fluid exposure to decreased water flea survival. Water fleas are unable to detect and avoid fracking fluid spills.²⁴¹ (See also entry for April 28, 2018.)

- February 28, 2019 – An American University team compared water quality parameters in 19 small streams in an intensely fracked area of southwestern Pennsylvania with those of 10 equivalent streams in western Maryland where fracking is banned and has never taken place. Streams in both study areas overlie the Marcellus Shale. Even after accounting for variations in forest cover, urban development, and historical impacts from coal mining, the researchers found significant differences in concentrations of certain salts and heavy metals, including arsenic. The results “imply that water quality has been affected by [shale gas] development in the Marcellus Shale region” and “support the idea that the Pennsylvania streams have received greater pollution inputs than have the Maryland streams.”²⁴²
- February 11, 2019 – The U.S. Justice Department reached a settlement with Antero Resources Corporation over claims that it violated the Clean Water Act at 32 different drilling and fracking-related sites in West Virginia. The violations involved unauthorized dumping of fracking waste into local waterways.²⁴³
- February 7, 2019 – The Karoo Basin in South Africa is a semi-arid region underlain by gas-containing shale. Its bedrock is also rich in uranium, and, consequently, the basin has a range of different naturally occurring radioactive materials, including radium and radon gas. As part of a baseline study prior to fracking, a South African team monitored the presence of radon in groundwater in 53 aquifers throughout the Karoo Basin. They found that water in seven sites had levels of radon above levels considered safe by the World Health Organization. They also observed lower levels in cool, deep aquifers and higher levels of radon in warm, shallow aquifers, where seasonal and annual fluctuations were common.²⁴⁴
- January 22, 2019 – Demand for water to use in fracking operations for oil extraction has more than doubled since 2016, according to data from Rystad Energy, an energy research intelligence company. In the Permian Basin alone, located in west Texas and southeastern New Mexico, water demand for fracking now exceeds the total U.S. demand in 2016.²⁴⁵
- January 7, 2019 – From samples of fracking wastewater in Alberta, a Canadian team isolated a previously unidentified class of contaminants, aryl phosphates, which degrade into diphenyl phosphate. Experiments showed that diphenyl phosphate does not bind to clay-rich soils. Therefore, its transportation into groundwater following fracking waste

spills would be swift. Further research showed toxic effects of low-level exposure of diphenyl phosphate on fish embryos and embryonic chick tissue. Noting that hundreds of fracking waste spills are reported in Alberta each year, the researchers expressed concern that diphenyl phosphate “may pose an environmental risk to aquatic ecosystems if released into the environment.”²⁴⁶

- November 28, 2018 – Drilling and fracking operations in the Marcellus Shale region are known to harm biodiversity and reduce the populations of aquatic invertebrate animals that are the basis of the food chain in streams. A research team working in West Virginia investigated whether an observed population decline in a species of bird, the Louisiana Waterthrush, might be related to loss of these aquatic invertebrates, which are its prey. While the results varied from year to year and loss of food resources did not wholly explain the declines in waterthrush populations in areas of active drilling and fracking, “collective evidence suggests there may be a shale gas disturbance threshold at which waterthrush respond negatively to aquatic prey community changes.”²⁴⁷
- November 19, 2018 – Methane can find its way into groundwater through naturally occurring fractures and fissures in shale deposits or through openings created by nearby drilling and fracking operations. A team led by Pennsylvania State University geochemist Susan Brantley sampled methane in drinking water wells in Pennsylvania with and without fracking, focusing on an area where fracking wells had been cited for contaminating nearby drinking water wells—in some cases with levels of methane high enough to be at risk for explosion. Researchers found that elevated methane levels in water wells near these fracking operations were accompanied by attendant spikes in iron and sulfates. These findings “document a way to distinguish newly migrated methane from pre-existing sources of gas.” They also showed that methane and ethane concentrations in local water wells increased after gas drilling compared with predrilling concentrations and that these levels remained elevated seven years after leaks were initially reported.^{248, 249} “We’ve documented that recent methane migration can change water chemistry in a way that can mobilize metals, such as iron, and release other unwanted chemical compounds, such as hydrogen sulfide,” said Joshua Woda, a co-author of the study, in a press statement.²⁵⁰

- November 6, 2018 – As reported by the news outlet, *WyoFile*, contaminated drinking water in Pavillion, Wyoming was likely caused by gas leaking from faulty gas wells as well as by leaks from 40 unlined pits that, for many years, served as dumps for drilling wastewater. This was the conclusion of three researchers, including two former U.S. Environmental Protection Agency (EPA) scientists, who had been investigating the pollution of Pavillion’s groundwater, including drinking water wells for at least 30 homes. The scientists presented their findings to the community in advance of publishing a peer-reviewed scientific journal article. Statistical analyses show a correlation between what was disposed in the pits and contaminants appearing in nearby drinking water wells. One of the former EPA scientists told community members that the Wind River Formation drinking water aquifer will likely never be cleaned up. A preliminary report from the EPA in 2011 about groundwater contamination in Pavillion was never finalized.²⁵¹
- October 21, 2018 – Fracking brine, among other factors, is contributing to “freshwater salinization syndrome,” according to a study that examined the increasing saltiness of North American inland waters. Freshwater salinization, in turn, alters the behavior of other chemicals in water, mobilizing diverse chemical mixtures that alter drinking water quality.²⁵²
- October 17, 2018 – An international team of researchers tested fracking wastewater from two different wells in the Fox River area of Alberta, Canada for presence of endocrine-disrupting compounds. Using laboratory assays, they found that organic extracts of the wastewater samples did indeed disrupt hormone signaling pathways in environmentally relevant concentrations, as might occur in an accidental spill, however the wastewater from the two different wells did so in two different ways. “The results suggest that the properties and origins of endocrine-disrupting compounds in [fracking wastewater] from Wells A and B are different, complicating our understanding of potential environmental effects of releases.”²⁵³
- September 4, 2018 – Chemicals from fracking wastewater dumped into the Allegheny River Watershed a decade ago are still accumulating in mussels that live there. Researchers working in Pennsylvania found elevated levels of strontium in the shells of freshwater mussels living downstream of a disposal facility that treated fracking wastewater and released it into streams between 2008 and 2011. (The practice was halted thereafter when heavy metals and radioactivity began rising in drinking water). Mussels living upstream of the treatment plant showed no such elevated levels. Strontium is an elemental metal and a contaminant of fracking waste. It is absorbed by living organisms in a similar manner to calcium. Because mussels excrete their shells in discreet layers that

can be aged (like tree rings), researchers were able to show that shell layers created after 2011, when dumping of fracking waste into streams had ceased, did not show a sharp reduction in strontium, suggesting that downstream sediments may act as a reservoir for persistent contaminants years after dumping stops.²⁵⁴ This is one of the first studies to show bioaccumulation of fracking contaminants in the bodies of living animals, which means that fracking contaminants are entering the food chain. The most endangered of all North American fauna, freshwater mussels are currently suffering a mass extinction event, as a likely result of degraded water quality.²⁵⁵ Commenting on these findings in a press statement, lead author Nathaniel Warner said, “We know that Marcellus development has impacted sediments downstream for tens of kilometers. And it appears it still could be impacted for a long period of time. The short timeframe that we permitted the discharge of these wastes might leave a long legacy.”²⁵⁶

- August 29, 2018 – Using reports created by the oil and gas industry, a Colorado State University team evaluated fracking waste spills in Weld County, Colorado and found that while large-scale operations generated less fracking wastewater per unit of energy generated, the total volume of spilled waste increased as the size of the operation increased. “The results suggest that employing fewer, large-scale operators would help reduce the overall volume of [wastewater] generated but not the overall volume spilled.” This study also found that the probability of groundwater contamination from those spills was not correlated with either the spill area or with the volume spilled. Instead, the depth to groundwater was a more accurate predictor of the probability of contamination, with shallow water tables at highest risk.²⁵⁷
- August 17, 2018 – With 548 permitted wells as of 2017, Belmont County is the most intensely fracked county in the state of Ohio. A Yale University team collected drinking water samples from 66 households in Belmont County that were located at varying distances away from well pads and analyzed them for the presence of fracking-related chemical contaminants. They also interviewed residents about their health symptoms. The primary goal of this exploratory study was to determine whether residential proximity to fracked wells was related to detection and concentrations of health-relevant drinking water contaminants. A second objective was to evaluate possible relationships between proximity to wells and health complaints in the community. The team found that all homes had at least one volatile organic compound or other organic compound above detectable levels and that prevalence of contaminants in drinking water, including

toluene, bromoform, and dichlorobromomethane, was higher in homes closer to the wells. Further, people who lived closer to multiple wells were more likely to report health problems including wheezing, stress, fatigue, and headache. This is the first study to concurrently collect drinking water samples, health information, and data on proximity to drilling and fracking operations.²⁵⁸

- August 15, 2018 – Using well information from the U.S. Energy Information Agency as well as state-based agencies, a Duke University team examined changes in water use intensity in U.S. drilling and fracking operations as horizontal drilling has evolved toward ever-long lateral wellbores. They found that water use for fracking operations increased by 770 percent per well between 2011 and 2016 across all U.S. shale basins. At the same time, the volume of fracking wastewater generated during the first year of extraction increased by up to 1,440 percent. “The steady increase of the water footprint of hydraulic fracturing with time implies that future unconventional oil and gas operations will require larger volumes of water for hydraulic fracturing, which will result in larger produced oil and gas wastewater volumes.” Noting that the freshwater used for hydraulic fracturing is either retained within the shale formation or returns as highly saline flowback waste that is often subsequently disposed of via deep well injection, the authors concluded that “the permanent loss of water use for hydraulic fracturing from the hydrosphere could outweigh its relatively lower water intensity” compared to other industrial uses of water, such as agriculture, where water is not lost to the hydrological cycle.²⁵⁹
- August 5, 2018 – Using water collected from streams and a reservoir near Middletown, Pennsylvania, a research team investigated how contamination with fracking chemicals, as during a spill event, alters the formation of disinfection byproducts when surface water is chlorinated for use as drinking water. They found a shift toward the creation of more brominated compounds. This finding has significant concerns for public health because brominated chemicals are not easily removed during the water treatment process and because discharge of bromide to surface waters remains largely unregulated.²⁶⁰
- July 19, 2018 – By simulating spills and discharge of fracking wastewater into rivers and streams, a Pennsylvania research team investigated the effects of fracking wastewater salinity on the creation of disinfection byproducts during drinking water treatment. They found evidence that the ions in salty fracking waste enhance the creation of these deleterious chemicals in ways that conventional water treatment processes cannot easily remove. “Further studies should focus on salinity removal technologies such as reverse osmosis, nanofiltration, electrodialysis, ion exchange, and lime/soda ash softening.”²⁶¹

- July 13, 2018 – Chemicals associated with fracking operations have been known to contaminate surface and ground water, and many of them have been identified as endocrine disruptors in mammals, raising questions about possible perturbations of other biological processes, such as immunity. Using tadpoles, an international team investigated how chemicals found in fracking wastewater might affect the developing immune system in amphibians. They found evidence for concern. Even at doses below those found in groundwater near spill sites, many exposed tadpoles died. “A first finding of this study is the startling toxicity of the [fracking chemical] mixture to tadpoles...it seems likely that the lethal effect results from the combined activity of some or all of these chemicals.” Lower doses significantly altered genes associated with immune functioning and made the developing frogs less able to fight off viral infections. “These findings suggest that [fracking-associated] water pollutants at low but environmentally relevant doses have the potential to induce acute alterations of immune function and antiviral immunity.”²⁶²
- July 4, 2018 – Wastewater samples from a newly fracked oil well in Colorado were examined over 220 days using assays to assess changing toxicity levels. The results revealed significant toxicity throughout well production and during the first 55 days of flowback, with peak toxicity occurring on the first day of flowback. Researchers also looked at the community of microbes (bacteria and archaea) living in the wastewater. Some of these organisms originated from deep in the shale formation and others from the source water used for fracking. These species rapidly changed in relative abundance to one another as the toxicity of the wastewater evolved over time. “Late stage produced water communities gradually became similar to those in the earliest sample of flowback water, indicating that early conditions have a great impact on the resident microbiota over the life of the well.”²⁶³
- June 21, 2018 – A Duke University-led lab study used mouse tissue cultures to investigate possible impacts of fracking wastewater exposure on the development of fat cells. They found that exposure to mixtures of 23 fracking chemicals, as well as raw stream water believed to be contaminated with fracking waste, promoted the growth of fat cells—even at very low concentrations. Collectively, these results show that fracking wastewater has the potential to impair metabolic health at levels found in the environment.²⁶⁴ In a statement to the media, co-author Chris Kassotis said, “We saw significant fat cell proliferation and lipid accumulation, even when wastewater samples

were diluted 1,000-fold from their raw state and when wastewater-affected surface water samples were diluted 25-fold.”²⁶⁵

- April 28, 2018 – A Canadian study found that the water flea (*Daphnia magna*) becomes immobilized when the surface of test waters are contaminated with fracking waste. This effect was persistent and occurred at concentrations significantly lower than is required to kill this common zooplankton outright. Immobilized *Daphnia* did not recover after 48 hours, could not feed, and became unable to shed their carapace, thus impeding reproduction. The evidence suggests that surfactants in fracking fluid together with floating hydrocarbons work together to reduce surface tension in ways that disallow *Daphnia* from re-entering the water column. “The current study shows that an important component of the toxicity of [fracking wastewater] to *Daphnia magna* is physical impairment. Depending on how the endpoint of a toxicity test is defined, this mode of action may not be accounted for in laboratory assessments used to determine risk. However, physical toxicity effects are likely to be important in environmental settings where [fracking wastewater] spills may occur.”²⁶⁶ (See also entry for March 5, 2019.)
- April 11, 2018 – A Drexel University team undertook a risk assessment of residential exposures to drinking water contaminated by fracking wastewater (flowback water). This simulation study found that within just eight hours—a realistic timeline for continual exposure due to a spill event—radioactive substances in the wastewater could produce demonstrable risks to human health, especially through the inhalation route. These radioactive compounds posed a greater threat to human health than other contaminants examined in this assessment, including arsenic, benzene, and vinyl chloride. “Radionuclides, which are known to exist in [fracking wastewater] as a result of occurring naturally within shale formations, pose a significant risk to human health and increase the likelihood of developing cancer in exposed individuals...median values for inhalation risk are at unacceptable levels. These exposures are due to the radionuclides aerosolizing from water primarily during showering.... Exposure to certain compounds of flowback water for only a few hours or days...can still present adverse effects.”²⁶⁷
- April 9, 2018 – An analysis of the bacterial community in 31 northwestern Pennsylvania trout streams showed that fracking activity altered the composition of species found in the sediment. Confirming the findings of previous studies, streams near drilling and fracking activity had significantly higher numbers of methane-metabolizing and methane-producing microorganisms, which are tolerant to acidic conditions. “Altogether, this study highlighted stable bacterial taxa responding to Marcellus shale activity and further

supplements a longitudinal correlation of increased acidity of stream water and fracking activity adjacent to headwater streams over five years.”²⁶⁸

- April 8, 2018 – Working in the South Fork Little Red River watershed in northern Arkansas, a research team found that populations of invertebrate animals were reduced downstream of drilling and fracking operations relative to upstream.²⁶⁹
- April 6, 2018 – Chemical characterization and toxicological testing of wastewater from fracked and conventionally drilled oil and gas wells in Pennsylvania were compared. Wastewater from both types of wells was equally toxic to animal and human cells growing in culture and was corrosive at high concentrations. This toxicity was not attributable to the presence of salts alone. Hydrocarbon chemicals were found in both well types and are known to be toxic to multiple human organs. “In vitro assays showed that normal cell survival, behavior, and morphology were severely impaired by short-term exposure to either type of sample at up to 1000-fold dilutions. ... Taken together, these results suggest that exposure to leaks or spills associated with either conventional or unconventional oil and gas extraction could potentially impact human health.”²⁷⁰
- April 5, 2018 – Led by researchers from the University of Missouri, a study conducted in Pavillion, Wyoming compared the effects of water pollution linked to fracking to effects from conventional drilling. Endocrine-disrupting chemicals were found in 22 groundwater samples taken near both kinds of wells. However, the results showed that contaminated groundwater collected near fracking sites was more disruptive to hormonal signaling in human cells than contaminated groundwater collected from conventional well pads. These results corroborate those of past studies.²⁷¹ In an associated news story in *WyoFile*, Christopher Kassotis, one of the co-authors of the new study, said, “We have now reported similar endocrine bioactivities across numerous unconventional oil/gas sampling regions, and other researchers are beginning to demonstrate similar effects in cell and animal models. These, above all else, lend strong support for our findings.”²⁷²
- March 5, 2018 – An exemption in the Safe Drinking Water Act allows hydraulic fracturing operations to escape federal regulation, leaving it up to individual states to determine how groundwater resources used for drinking are protected during fracking

operations that take place on lands without federal or tribal mineral rights. A research team from Stanford University, University of California, Berkeley, and Lawrence Berkeley National Laboratory assessed these state-based oil and gas regulations in 17 different states. They found that the definitions of “protected groundwater” are vague, inconsistent and, very often, offer less protection than federal regulations. For example, in Alabama and New Mexico, protection of drinking water appears discretionary. In Colorado and Texas, protection of drinking water depends on the location of the oil and gas fields. In Illinois, protection during fracking only applies to horizontal wells. In California, drinking water must be monitored but not explicitly protected. Concluding from these findings that the nation’s drinking water resources are vulnerable to contamination from oil and gas extraction and wastewater disposal, the research team recommended that criteria defined by the EPA for an underground drinking water source be consistently used to define protected groundwater in state-based oil and gas regulations.²⁷³

- February 15, 2018 – A UK team used reports from the Texas Railroad Commission (1999-2015) and the Colorado Oil and Gas Conservation Commission (2009-2015) to examine spill rates from oil and gas well pads. They found that the spill rate in both Colorado and Texas significantly increased over the recorded time period, with equipment failure cited as the most common cause. In Colorado, 33 percent of the spills were discovered during site remediation and random site inspections. Using these data, the team predicted that a UK fracking industry would likely experience a spill for every 19 well pads developed.²⁷⁴
- January 31, 2018 – Researchers in Arkansas found that water withdrawals for fracking operations can dangerously deplete water levels in up to 51 percent of streams in ways that potentially threaten drinking water supplies, damage aquatic life, and disrupt recreation. “There is potential for these withdrawals to cause water stress,” the paper concluded.²⁷⁵ Water stress represents risk of water scarcity for people caused by increases in economic costs or altered stream flow that results in loss of aquatic biodiversity and ecosystem functioning.
- January 27, 2018 – Fracking wastewater is a developmental toxicant to zebra fish embryos, according to results of a laboratory study conducted by a Canadian team of researchers. Exposure to various concentrations of fracking flowback and produced

water, collected from well sites in Alberta, was linked to spinal and heart abnormalities and patterns of altered gene expression consistent with endocrine disruption.²⁷⁶

- January 23, 2018 – An Ohio State University team developed and used numerical models to simulate how methane from a leaking well could migrate into different types of drinking water aquifers. Their results showed that rapid, long-distance gas flow was most likely to occur when a pulse of gas under high pressure from a faulty gas well entered into a fractured rock aquifer. In these cases, methane can easily migrate a distance of 1 kilometer within a week and in many different directions, including laterally away from the natural gas well. Current efforts to evaluate natural gas leakage from faulty wells “likely underestimate contributions from small-volume, low-pressure leakage events,” which require extended periods of environmental monitoring.²⁷⁷
- January 16, 2018 – An editorial in the journal *Groundwater* warned researchers against being too quick to dismiss the presence of methane in groundwater near fracking sites as “always naturally occurring,” especially in places where no pre-drill baseline data are available or in studies where average methane levels are being compared. Noting that the geological conditions that facilitate the natural migration of hydrocarbons are often “muddled, obfuscating the presence of hydrocarbon pollution due to gas leaking from production wells,” the editorial encouraged study designs that make use of odds-ratio tests and geochemical tracers. Fractured rocks within shallow aquifers, in particular, are concerning “both in terms of their potential for facilitating rapid ... gas flow, and their inherent geometric complexity, which impact hydrocarbon gas transport mechanisms.”²⁷⁸
- January 16, 2018 – The Pennsylvania Department of Environmental Protection determined that fracking wastewater that had leaked from a storage pit contaminated groundwater and rendered a natural spring used for drinking water in Greene County undrinkable.²⁷⁹
- January 9, 2018 – A University of Texas team collected groundwater samples from across shale basins in Texas and reported on the discovery of opportunistic, pathogenic bacteria in fracking-impacted water wells in Texas. These results raise questions about fracking’s effects on the microbial ecology of aquifers. Commenting on their findings, the researchers noted, “The results were quite surprising. Not only did we find that various opportunistic pathogens could survive in the presence of hydrocarbon gases and chemical additives, they appeared to thrive and exhibited robust resistance profiles to

multiple antibiotics. We even observed that certain pathogens were resilient to high levels of chlorination.”²⁸⁰

- December 11, 2017 – A report by the *Texas Observer* investigated groundwater depletion by fracking operations in west Texas at the southern edge of the Ogallala Aquifer. Groundwater conservation districts lack legal financial resources to restrict groundwater pumping or even compel metering on water wells that would monitor exactly how much water is pumped. In Howard County alone, water used for fracking is now believed to constitute about 20 percent of average annual water use.²⁸¹
- November 16, 2017 – The 2005 Energy Policy Act prohibited the EPA from regulating fracking under the Safe Drinking Water Act and from requiring that operators disclose their chemicals. According to an investigation by *InsideClimate News*, the scientific study that justified this provision (which is widely known as the Halliburton loophole) was the subject of a whistleblower complaint. The study was also disavowed by its authors, who said the conclusion of the report—that fracking posed no risk to groundwater—was not supported by the evidence. These authors removed their names from the final document. Interviewed for the story, one of these authors said that the belief that fracking was safe for water was a foregone conclusion at the EPA under George W. Bush. “What we would have said in the conclusion is that there is some form of risk from hydraulic fracturing to groundwater. How you quantify it would require further analyses, but, in general, there is some risk.”²⁸²
- November 9, 2017 – As part of a preliminary study, a Texas team assessed the groundwater microbiome in a rural area of southern Texas where farming and fracking co-exist. Each of the sampled water wells had a unique community of microorganisms living in the water. The dominant bacteria were denitrifying species that transform nitrates into gaseous nitrogen or those that break apart hydrocarbon molecules. Earlier studies have postulated that fracking can alter the chemical composition of groundwater and change the species composition of the microbial communities living within it. The results of this study “do not provide a definitive link between [fracking] or agricultural activities and the groundwater microbiome; however, they do provide a baseline measurement of bacterial diversity and quantity in groundwater located near these anthropogenic activities.”²⁸³

- November 1, 2017 – In Oklahoma, horizontal wells can be fracked within 600 feet of older, vertical wells that do not use fracking. Oil companies in Oklahoma that extract oil using conventional, vertical wells alleged that hundreds of their wells have been inundated by fluids from nearby horizontal wells that use high-volume hydraulic fracturing, as documented by *E&E News*. Vertical well operators have raised questions about whether these “frack hits” from nearby horizontal wells that have flooded their own wells have also reached the groundwater. “Logic said it will impact [groundwater],” said one driller. “There was water coming up out of the ground. There was enough pressure to bring it to the surface.” Small operators of vertical wells, organized as the Oklahoma Energy Producers Alliance (OEPA), released a study estimating that, in just one county alone, there were 400 cases of frack fluid from horizontal wells flooding nearby vertical wells.^{284, 285}
- October 31, 2017 – A study of fracking wastewater disposed of in rivers and streams found that chemical contaminants in the waste were transformed into more toxic substances when they chemically reacted with chlorinated compounds discharged from downstream drinking water treatment plants. The result was dozens of different, brominated and iodinated disinfection byproducts (DBPs). A lab analysis found that all were highly toxic to mammalian cells. Conventional water treatment practices do not remove these chemicals. “It is likely that in oil- and gas-impacted drinking water sources, iodo-phenolic DBPs could form at significant levels, particularly in cases in which chloramination is used.”²⁸⁶
- October 18, 2017 – Researchers concerned about reports of skin rashes, gastrointestinal distress, and breathing problems among people who live near drilling and fracking operations found increased levels of certain harmful bacteria in private water wells impacted by fracking in the Barnett and Eagle Ford Shale areas in Texas. These results raise questions about whether drilling and fracking activities could alter the communities of microorganisms in groundwater in ways that pose health risks. According to one of the lead authors of the study, interviewed in the *Dallas News*, “the potential contribution of these microbes to these health effects is probably understudied, underappreciated, unknown.”^{287, 288}

- August 3, 2017 – Due to permitting errors and a mix-up in records 30 years ago, wastewater from drilling operations in California was mistakenly injected directly into drinking water aquifers. Six years after the discovery of the problem, 175 wastewater wells that were illegally injecting into protected aquifers have been shut down, but hundreds more are still operating. An investigation by KQED Science revealed that California state water regulators know very little about the actual impact of those injections on the state’s drinking water reserves. “State water regulators say they hope to figure out what the larger impacts have been in years ahead, but have no set timeline. The risk is that they’ve allowed oil companies to contaminate drinking water aquifers to such an extent that Californians may have permanently lost those sources of fresh water.”²⁸⁹ An earlier investigation by KQED Science revealed that illegal wastewater wells would still be allowed to operate while the necessary paperwork was filed.²⁹⁰
- July 12, 2017 – In western Pennsylvania, a team of researchers looked at sediments in the Conemaugh River watershed downstream of a treatment plant that was specially designed to treat fracking wastewater. The researchers found contamination for many miles downstream with fracking-related chemicals that included radium, barium, strontium, and chloride, as well as endocrine-disrupting and carcinogenic compounds. The peak concentrations were found in sediment layers that had been deposited during the years of peak fracking wastewater discharge. Elevated concentrations of radium were detected as far as 12 miles downstream of the treatment plant and were up to 200 times greater than background. Some stream sediment samples were so radioactive that they approached levels that would, in some U.S. states, classify them as radioactive waste and necessitate special disposal.^{291, 292}
- May 31, 2017 – A U.S. Geological Survey (USGS) team sampled drinking water wells near drilling and fracking sites in the Eagle Ford, Fayetteville, and Haynesville Shale basins and found detectable levels of methane and benzene. However, the sources of these contaminants were unclear, and, given the slow travel time of groundwater, “decades or longer may be needed to fully assess the effects of potential subsurface and surface releases of hydrocarbons on the wells.”²⁹³

- May 1, 2017 – A study examining the impacts of drilling and fracking operations on public drinking water in Pennsylvania found evidence of contamination when drinking water source intakes were located within one kilometer (.62 miles) of a well pad. Noting that many Pennsylvanians living near well pads drink bottled water, the authors concluded, “our results suggest that these perceived risks may in fact be justified.”²⁹⁴ (See also entry below for October 13, 2016.)
- April 19, 2017 – Using data from the South Coast Air Quality Monitoring District, a team of researchers in California compared chemicals used in fracking operations with those used in the routine maintenance of conventional oil and gas wells where chemicals are used to aid in drilling, for corrosion control, to clean the wellbore, and to enhance oil recovery. They found significant overlap in both the types and amounts of chemicals used. “The results of this study indicate regulations and risk assessments focused exclusively on chemicals used in well-stimulation activities may underestimate potential hazard or risk from overall field chemical-use. . . . Our analysis shows that hydraulic fracturing is just one of many applications of hazardous chemicals on oil and gas fields.”²⁹⁵
- April 5, 2017 – A three-year study in West Virginia led by scientists at Duke University assessed surface water and groundwater drawn from drinking water wells both before and after drilling and fracking began in the region. Using geochemical techniques, including a suite of tracers that help distinguish naturally occurring methane and salts from those contained in fracking fluid, the researchers found no evidence of groundwater contamination. They did, however, document threats to surface water from fracking wastewater spills.²⁹⁶ In an accompanying statement, the researchers noted, “What we found in the study area in West Virginia after three years may be different from what we see after 10 years because the impact on groundwater isn’t necessarily immediate.”²⁹⁷
- Feb 21, 2017 – Between 2005 and 2014, researchers surveyed spill record data from drilling and fracking operations in four states (Colorado, New Mexico, North Dakota, and Pennsylvania). During these nine years, they documented 6,678 total spills, or about five spills each year for every 100 wells. Between 2 and 16 percent of wells reported a spill each year. Half of all spills were related to storage and transport of fluids through flow lines. The authors also found that the chances of spills are highest during the first three

years of a well's life and that spill reporting requirements differ markedly from state to state, making impossible the task of comparing states or creating a national picture.^{298, 299}

- January 31, 2017 – California is the only state that allows fracking waste to be held in unlined, open pits, creating risks for groundwater contamination. A California Water Boards investigation found that, as of January 2017, 1,000 such pits were operational, with 400 lacking required state permits. The vast majority is located in Kern County.³⁰⁰
- December 14, 2016 – To better understand the impact of fracking fluid spills on aquatic animals, scientists at the University of Alberta exposed rainbow trout in laboratory tanks to various dilutions of fracking fluids. Even at very low exposures, the fish experienced adverse effects, including alterations in liver functioning and disruption of hormonal pathways. [This study was partially funded by industry.]³⁰¹
- December 13, 2016 – The final version of the EPA's six-year, \$29 million study on the impacts of hydraulic fracturing on the nation's drinking water confirmed that fracking activities have caused contamination of water resources in the United States, and it traced the various routes by which drinking water can be impacted by fracking. Documented cases of drinking water contamination have resulted from spills of fracking fluid and fracking wastewater; discharge of fracking waste into rivers and streams; and underground migration of fracking chemicals, including gas, into drinking water wells. Depletion of aquifers caused by water withdrawals has created other impacts.^{302, 303, 304, 305} The final EPA report detailed the problem of fracking-related drinking water contamination in three communities—Pavillion, Wyoming; Dimock, Pennsylvania; and

Parker County, Texas.³⁰⁶ Summing up the report, then-EPA Deputy Administrator Tom Burke said in a statement to *American Public Media*, “We found scientific evidence of impacts to drinking water resources at each stage of the hydraulic fracturing cycle.”³⁰⁷ (See also the entry for June 5, 2015, which describes the contents of the 2015 draft report.)

- December 1, 2016 – According to a review paper that examines the potential environmental impacts of oil and gas wastewater, about 5 percent of fracking waste is accidentally or illegally spilled. Almost all of the rest is transported off site and injected into disposal wells that are drilled into porous geological formations. In North Dakota’s Bakken Shale, disposal wells are located within miles of the well pad, and the wastewater can travel there via pipeline. In Pennsylvania’s Marcellus Shale, drilling activity exceeds the capacity for disposal of waste in local wells and must be trucked out of state.³⁰⁸
- November 4, 2016 – A critical review of potential routes of water contamination from drilling and fracking operations in the Bakken Shale noted that the high salinity of fracking wastewater minimizes its recycling options and thus contributes to the need for disposal wells. Transportation of large volumes of waste to these wells, via truck or pipeline, presents opportunities for large spills that can threaten groundwater.³⁰⁹
- October 16, 2016 – A team of scientists led by researchers at the Lawrence Berkeley National Laboratory evaluated chemicals used for fracking in California oil fields. Chemical additives included a wide variety of solvents in large amounts, as well as other toxic substances, including biocides and corrosion inhibitors.³¹⁰
- October 14, 2016 – One of the first studies to investigate the impacts of fracking on the ecology of streams found that fracking “has the potential to alter aquatic biodiversity and methyl mercury concentrations at the base of food webs.” The researchers sampled 27 remote streams in the Marcellus Shale basin of Pennsylvania where drilling and fracking is taking place. They showed that methyl mercury levels in stream sites where fracking occurs were driven upwards by higher acidity and lower numbers of macroinvertebrates. In streams with the highest numbers of fracking fluid spills, “fish diversity was nil,” and

in some cases, there were no fish at all, including in streams previously classified as high-quality brook trout habitat. “Fracking and flowback fluids can contain various highly acidic agents, organic and inorganic compounds, and even Hg [mercury]. The flowback fluids can reach nearby streams through leaking wastewater hoses, impoundments, and lateral seepage and blowouts, as well as by backflow into the wellhead. Flowback water reaching streams can . . . decrease aquatic biodiversity. . . . Lowered stream pH increases Hg solubility, leading to increased bioaccumulation in food webs.”³¹¹

- October 13, 2016 – Researchers at Pennsylvania State University and Ohio State University combined GIS data on drilling and fracking activities in Pennsylvania and Ohio with household data on bottled water purchases. They found that yearly household purchases of bottled water increased as local drilling and fracking intensity increased. This “averting behavior” is a measure of perceived risk. In 2010, averting-behavior expenditures in the form of bottle water purchases by people living in Pennsylvania’s shale counties totaled \$19 million.³¹² (A subsequent study suggests that those engaged in tapwater averting behaviors in Pennsylvania have evidence-based reasons to be concerned. See entry above, for May 1, 2017.)
- September 22, 2016 – Using the agency’s list of 1076 chemicals that have reported use as ingredients in hydraulic fracturing fluid, EPA scientists developed a framework to analyze and rank subsets of chemicals in order to better understand which fracking-related chemicals pose the greatest risk to drinking water. Their model collates multiple lines of evidence. For example, data on inherent toxicity are combined with data on occurrence and propensity for environmental transport. In the absence of local data on actual human exposures, this model can serve as a qualitative metric to “identify chemicals that may be more likely than others to impact drinking water resources.”³¹³
- September 16, 2016 – A reconnaissance analysis of groundwater in the Eagle Ford Shale region in southern Texas found sporadic detections of multiple VOCs and dissolved gas, providing evidence that “groundwater quality is potentially being affected by neighboring [drilling and fracking] activity, or other anthropogenic activities, in an episodic fashion.” The authors called for a more extensive investigation of possible groundwater contamination in the Eagle Ford basin.^{314, 315}

- July 11, 2016 – An interdisciplinary team led by University of Colorado researchers found methane in 42 water wells in the intensely drilled Denver-Julesburg Basin where high volume, horizontal fracking operations began in 2010. By examining isotopes and gas molecular ratios, the researchers determined that the gas contaminating these wells was thermogenic in origin, rather than microbial, and therefore had migrated up into the groundwater from underlying oil- and gas-containing shale. The steady rate of well contamination over time—two cases per year from 2001 to 2014—suggests that well failures, rather than the process of hydraulic fracturing itself, was the mechanism that created migration pathways for the stray gas to reach drinking water sources. Of the 42 affected wells, 11 had already been identified by state regulators as suffering from “barrier failures.”³¹⁶ Duke University geochemist Avner Vengosh, who was not an author of the paper, commented on the study in an accompanying article in *InsideClimate News*: “The bottom line here is that industry has denied any stray gas contamination: that whenever we have methane in a well, it is always preexisting. The merit of this is that it’s a different oil and gas basin, a different approach, and it’s saying that stray gas could happen.” In this same article, *InsideClimate News* reported that national standards for well construction do not exist, nor are there laws governing the type of cement that is used to seal the wellbore and prevent leaks.³¹⁷
- May 24, 2016 – ATSDR conducted a public health evaluation using groundwater data gathered in 2012 by the EPA from 64 private drinking water wells in Dimock, Pennsylvania where natural gas drilling and fracking activities began in 2008 and where residents began reporting problems with their water shortly thereafter. The agency found that water samples collected from 27 Dimock wells contained contaminants “at levels high enough to affect human health.” These included methane, salts, organic chemicals, and arsenic. In 17 wells, levels of methane were high enough to create risk of fire or explosion.³¹⁸ Methane levels were not assessed in wells prior to the start of fracking activities in the area. Hence, the study is limited by lack of pre-drilling baseline data, and investigators did not attempt to determine the source of the contaminants. However, in its focus on identifying health impacts, ATSDR’s evaluation is a more comprehensive study than that conducted four years earlier by the EPA and calls into question its earlier, more reassuring conclusions.^{319, 320}

- May 9, 2016 – Sampling downstream of a fracking wastewater disposal facility in West Virginia, a USGS team documented changes in microbial communities and found evidence indicating the presence of fracking waste in water and sediment samples collected from Wolf Creek in West Virginia. Specifically, the researchers documented increased concentrations of barium, bromide, calcium, sodium, lithium, strontium, iron, and radium downstream of the disposal well.³²¹ In a *Washington Post* story about this study, lead author Denise Akob said that the key take-away message “is really that we’re demonstrating that facilities like this can have an environmental impact.”³²² (This study was done in collaboration with Susan Nagel’s team, which studied endocrine-disrupting activity in this same stream. See entry below for April 6, 2016.)
- April 30, 2016 – As part of an investigation based on aerial photographs taken by emergency responders during spring 2016 flooding, the *El Paso Times* documented plumes and sheens of chemicals from tipped-over storage tanks and inundated oil wells and fracking sites entering rivers and streams. “Many of the photos shot during Texas’ recent floods show swamped wastewater ponds at fracking sites, presumably allowing wastewater to escape into the environment—and potentially into drinking-water supplies.”³²³
- April 27, 2016 – Using geochemical and isotopic tracers to identify the unique chemical fingerprint of Bakken region brines, a Duke University study found that accidental spills of fracking wastewater have contaminated surface water and soils throughout North Dakota where more than 9,700 wells have been drilled in the past decade. Contaminants included salts as well as lead, selenium, and vanadium. In the polluted streams, levels of contaminants often exceeded federal drinking water guidelines. Soils at spill sites showed elevated levels of radium.³²⁴ The study concluded that “inorganic contamination associated with brine spills in North Dakota is remarkably persistent, with elevated levels of contaminants observed in spill sites up to 4 years following the spill events.” In a comment about this study, lead author and Duke University geochemist Avner Vengosh said, “Until now, research in many regions of the nation has shown that contamination from fracking has been fairly sporadic and inconsistent. In North Dakota, however, we

find it is widespread and persistent, with clear evidence of direct water contamination from fracking.”³²⁵

- April 6, 2016 – A research team led by Susan Nagel at the University of Missouri traced a spike in endocrine-disrupting activity in a West Virginia stream, Wolf Creek, to an upstream facility that stores fracking wastewater. Levels detected downstream of the waste facility were above levels known to create adverse health effects and alter the development of fish, amphibians, and other aquatic organisms. Endocrine-disrupting compounds were not elevated in upstream sections of the creek.^{326, 327} (See also entry for May 9, 2016 above.)
- March 29, 2016 – A study by Stanford University scientists determined that fracking and related oil and gas operations have indeed contaminated drinking water in the town of Pavillion, Wyoming where residents have long complained about foul-tasting water. The researchers found substances in the water that match those used in local fracking operations or found in nearby pits used for the disposal of drilling waste. Chemical contaminants included benzene, a known carcinogen, and toluene, a neurotoxicant. Possible mechanisms for contamination include defective cement well casings; spills and leaks from disposal pits; and underground migration of chemicals into aquifers from the fracked zone, which, in this area, is quite shallow. Also, in the Pavillion area, operators sometimes fracked directly into underground sources of water.³²⁸ One of the authors of this study, Dominic DiGiulio, was also a lead scientist on the EPA’s earlier aborted investigation of Pavillion’s drinking water. (See entry for December 6, 2015 below.) In an interview about his new research, DiGiulio said that his findings raise concerns about similar water pollution in other heavily fracked regions. “Pavillion isn’t geologically unique in the West, and I’m concerned about the Rocky Mountain region of the U.S. The impact on [underground drinking water sources] could be fairly extensive. Pavillion is like a canary in a coal mine and we need to look at other fields.”³²⁹ Co-author Rob Jackson noted, “There are no rules that would stop a company from doing this anywhere else.”³³⁰

- February 22, 2016 – Relying on voluntary disclosures reported to the FracFocus registry and a list compiled by the U.S. Congress, a German team surveyed the physiochemical properties of chemicals used in hydraulic fracturing fluid to evaluate their environmental fate and potential toxicity. Common ingredients included those known to contaminate groundwater, such as solvents, as well as those known to react strongly with other chemicals, such as biocides and strong oxidants, indicating that almost certainly, new chemical products are formed during the process of fracking and its aftermath. Hence, non-toxic additives could potentially react with other substances to create harmful byproducts. The authors conclude that a comprehensive assessment of risks would require an unabridged list of the chemical additives used for fracking, and they call for full disclosure.^{331, 332}
- February 9, 2016 – An investigation of water contamination in the Barnett Shale by ABC-affiliate station WFAA in Dallas found numerous violations by operators who ignored regulations that require sealing vertical well pipes with a cement sheath to protect groundwater from stray gas and other vapors that might escape and migrate upwards into overlying aquifers. The WFAA report said that the Texas Railroad Commission, which oversees drilling and fracking operations in Texas, has failed to respond to alleged violations of a rule that requires cement seals around steel well casings in geological zones where drilling has penetrated layers of rock containing oil and gas deposits.³³³
- February 8, 2016 – An investigation by the *Columbus Dispatch* revealed that the amount of water that operators use for hydraulic fracturing in Ohio gas wells increased steadily from 2011 to 2015. The total amount of water increased, as did the volume of water used per well—from an average of 5.6 million gallons per well in 2011 to 7.6 million in 2014. The reason is that the horizontally drilled holes beneath each well have become longer, and these require more water during the fracking process.³³⁴
- February 2016 – In a lengthy account to Congress on the status of the underground waste injection well program that is overseen by the EPA, the U.S. Government Accountability Office (GAO) reported that the agency “has not consistently conducted oversight activities necessary to assess whether state and EPA-managed programs are protecting underground sources of drinking water” from contamination by fracking waste. Specifically, the GAO took the EPA to task for failure to require well-specific inspections, collect data on enforcement actions, review permitting requirements by state regulatory agencies, or analyze the resources the agency would need to do all the above to adequately oversee the Underground Injection Control program. The GAO noted that it

had once before, in 2014, previously found the EPA negligent in its responsibilities to monitor drinking water sources for possible contamination with fracking waste.³³⁵ (See entry below for September 23, 2014.)

- January 6, 2016 – Yale School of Public Health researchers analyzed more than 1,021 chemicals either used in fracking fluid or created during the process of hydraulic fracturing. They found that 781 of these chemicals lacked basic toxicity data. Of the 240 that remained, 157 were reproductive or developmental toxicants. These included arsenic, benzene, cadmium, formaldehyde, lead, and mercury.³³⁶ Commenting on this study, lead author Nicole Deziel said, “This evaluation is a first step to prioritize the vast array of potential environmental contaminants from hydraulic fracturing for future exposure and health studies. Quantification of the potential exposure to these chemicals, such as by monitoring drinking water in people’s homes, is vital for understanding the public health impact of hydraulic fracturing.”³³⁷
- December 15, 2015 – A research team led by geologist Mukul Sharma from Dartmouth College discovered that chemical reactions between fracking fluid and rock can contribute to the toxicity of fracking wastewater. Specifically, the researchers found that fracking fluid can chemically react with the fractured shale in ways that cause barium, a toxic metal, to leach from clay minerals in the Marcellus Shale.^{338, 339}
- December 6, 2015 – The *Caspar Star Tribune* investigated the EPA’s decision to transfer its study of possible fracking-related drinking water contamination in Pavillion, Wyoming to a state agency in 2013. Preliminary data from the EPA suggested that drilling and fracking operations had contaminated drinking water supplies. To date, the state study has found no definitive link between drilling and water contamination. Interviews with officials and documents obtained under the Freedom of Information Act revealed that the EPA had bowed to political pressure from state officials and industry representatives and that Wyoming regulators narrowed the scope of the study considerably and conducted little fieldwork.³⁴⁰ (See also entry above for March 29, 2016.)

- November 19, 2015 – The Science Advisory Board (SAB) for the EPA reviewed the EPA’s June 2015 draft assessment of fracking’s impacts on drinking water, and challenged some of the summary statements that accompanied it, saying that they were over-generalized and not always aligned with the data in the report itself. Specifically, the SAB said, in a draft review, that the data cited by the report were too limited to support the headlined claim in the executive summary that drinking water impacts were neither “widespread” nor “systemic.” The SAB also critiqued the study for downplaying local impacts in its conclusions, noting that these impacts can sometimes be severe.³⁴¹
- October 19, 2015 – A six-month investigation by *Penn Live* found long-standing “systemic failures” on the part of the Pennsylvania Department of Environmental Protection (PA DEP) to enforce regulations governing drilling and fracking operations. Lack of oversight and reliance on industry self-policing have been the hallmarks of Marcellus Shale development for the past ten years, in violation of Pennsylvanians’ constitutional right to clean air and water. Among the findings of this investigation: chronically leaking wastewater impoundments for which no fines or notices were issued to the operator; laboratory coding systems designed to obscure possible detections of certain chemical contaminants in residents’ drinking water; and lack of inspections at well sites.³⁴²
- October 13, 2015 – An international team of researchers found detectable levels of multiple organic chemical contaminants in private drinking water wells in northeastern Pennsylvania where fracking is practiced. One of the compounds was a known additive of fracking fluid. Chemical fingerprinting and noble gas isotopes were used to determine if the contaminants most likely originated from surface spills at the well site or via upward transport from the shale itself. The organic pollutants found in the water did not contain chemical markers—certain elements and salts—that would indicate migration from deep geological strata. The authors concluded that “the data support a transport mechanism...to groundwater via accidental release of fracturing fluid chemicals derived from the surface rather than subsurface flow of these fluids from the underlying shale formation.”^{343, 344}
- September 23, 2015 – A team of researchers, examining how natural gas drilling and fracking operations across the nation affect creeks, streams and rivers, developed a predictive model and vulnerability index for surface water. They found that “all shale plays, regardless of location, had a suite of catchments that spanned highly degraded to

those that are less altered and naturally sensitive to alteration.” Surface water in Pennsylvania’s Marcellus Shale region is classified by this model as vulnerable to fracking-related impacts because of steep slopes and loose, erodible soils within the watersheds.³⁴⁵

- July 30, 2015 – As reported by the *Los Angeles Times*, unlined waste pits and hillside spraying of oil-field wastewater have contaminated groundwater in Kern County, California. Five of six monitoring wells in the 94-acre waste site showed high levels of salt, boron, and chloride, but it is not known how far and fast the contaminated plume has traveled.³⁴⁶
- July 21, 2015 – By surveying records for 44,000 wells fracked between 2010 and 2013, researchers from Stanford University, Duke University, and Ohio State University attempted a first-ever assessment of the range of depths at which fracking occurs across the United States. They found that many wells are shallower than widely presumed.³⁴⁷ As the authors noted, vertical fractures are able to propagate 2,000 feet upward, and hence, “shallow hydraulic fracturing often has greater potential risks of contamination than deeper hydraulic fracturing does.” This study showed that drinking water sources may be more vulnerable from upward migration of fracking contaminants than previously presumed. Surprisingly, the researchers found no strong relationship between depth and the volume of water and chemicals used for fracking. Many wells were both shallow and water-intensive, with significant variation in water use from state to state.³⁴⁸
- July 9, 2015 – A multi-volume report from the California Council of Science and Technology (CCST) found threats to groundwater in California from several parts of the fracking lifecycle, most notably from toxic wastewater. First, wastewater from California fracking operations is sometimes used for crop irrigation, in which case contaminants may seep from the surface of agricultural areas into groundwater. Second, nearly 60 percent of fracking wastewater in California is disposed of in unlined, open-air pits, a practice that is banned in almost all other states. There are 900 such waste disposal pits in the state, most of which are located in Kern County. Third, for many years, fracking wastewater in California has been mistakenly sent, via injection wells, directly into protected aquifers containing clean freshwater.³⁴⁹ California’s Division of Oil, Gas and Geothermal Resources allowed fracking wastes to be injected into aquifers that it

believed were exempt from the U.S. Safe Drinking Water Act. Conceding this mistake, the agency has shut down 23 injection wells for fracking waste disposal and established a two-year timetable for phasing out other wells injecting waste into aquifers that should have been protected.³⁵⁰ Fracking also threatens California's groundwater resources through water consumption, according to the CCST study. While this volume of water represents a small percentage of overall annual water consumption in California, fracking-related water use is, the study noted, disproportionately concentrated in areas of the state already suffering from water shortages. Further drawdowns of these aquifers may interfere with agricultural and municipal water needs.³⁵¹ In addition, because the oil-containing rock layers in California are located closer to the surface than in other states, the state's groundwater is potentially vulnerable to chemical contamination through vertical faults and fissures and via old and abandoned wells. The absence of evidence for direct contamination of groundwater by fracking, the study concluded, reflects absence of investigation rather than evidence of safety.³⁵²

- June 30, 2015 – The USGS released the first nationwide map of water usage for hydraulic fracturing. It shows wide geographic and temporal variation in the amount of water used to frack a single well. In general, gas wells consume more water per well (5.1 million gallons on average) than oil wells (4 million gallons). Median annual water volumes needed to frack a single horizontal oil or gas well increased dramatically—by a factor of 25 or more—between 2000 and 2014. A typical gas or oil well that is horizontally fracked now requires between six and eight Olympic-sized swimming pools of water. In 2014, the majority (58 percent) of new hydraulically fracked oil and gas wells were horizontally drilled. The watersheds where the most water was consumed for hydraulic fracturing are mostly located in southern or southwestern states and correspond to the following shale formations: the Eagle Ford and Barnett Shales in Texas; the Haynesville-Bossier Shale in Texas and Louisiana; the Fayetteville Shale in Arkansas; the Tuscaloosa Shale in Louisiana and Mississippi; and the Woodford Shale in Oklahoma. The Marcellus and Utica Shales—which underlie watersheds in parts of Ohio, Pennsylvania, West Virginia, and New York—were also in the top seven water-consuming shale plays in the United States.³⁵³
- June 26, 2015 – A decade-long USGS study of 11,000 public drinking water wells in California—nearly all the groundwater used for public supply—found high levels of potentially toxic contaminants in about 20 percent of the wells, affecting about 18 percent

of the state's population.³⁵⁴ Although the study did not specifically investigate contaminants from oil and gas extraction, it does provide evidence for farm irrigation draining into groundwater, raising questions about the possible contamination of drinking water aquifers from the reuse of fracking wastewater for crop irrigation.³⁵⁵

- June 16, 2015 – A University of Texas research team documented widespread drinking water contamination throughout the heavily drilled Barnett Shale region in northern Texas. The study, which analyzed 550 water samples from public and private water wells, found elevated levels of 19 different hydrocarbon compounds associated with fracking (including the carcinogen benzene and the reproductive toxicant, toluene), detections of methanol and ethanol, and strikingly high levels of 10 different metals.³⁵⁶ “In the abstract, we can’t state that unconventional oil and gas techniques are responsible,” the lead author, Zachariah Hildenbrand, said in a media interview. “But when you get into areas where drilling is happening, you find more instances of contamination. It’s not coincidental. There are causes for concern.”³⁵⁷
- June 5, 2015 – The EPA’s long-awaited 600-page draft report on the potential impacts of fracking for drinking water resources confirmed specific instances of drinking water contamination linked to drilling and fracking activities. The report also identified potential mechanisms, both above and below ground, by which drinking water resources can be contaminated by fracking. In some cases, drinking water was contaminated by spills of fracking fluid and wastewater. In other cases, “[b]elow ground movement of fluids, including gas . . . have contaminated drinking water resources.” The EPA investigators documented 457 fracking-related spills over six years but acknowledged that they do not know how many more may have occurred. Of the total known spills, 300 reached an environmental receptor such as surface water or groundwater. The EPA also conceded that insufficient baseline drinking water data and a lack of long-term systematic studies limited the power of its findings. The EPA investigation confirmed a number of specific instances where these potential mechanisms did indeed lead to drinking water contamination. An assertion in the EPA’s accompanying press release that it had not found “widespread, systemic impacts to drinking water resources” was quoted out of context by many media sources as proof that fracking poses little threat to drinking water. To the contrary, this report confirmed that drilling and fracking activities have contaminated drinking water in some cases and acknowledged that it cannot ascertain

how widespread the problem was due to insufficient data.³⁵⁸ EPA Science Advisor Thomas A. Burke later clarified that the report does not show that fracking is safe. Burke said, “That is not the message of this report. The message of this report is that we have identified vulnerabilities in the water system that are really important to know about and address to keep risks as low as possible.”³⁵⁹

- May 19, 2015 – A Pennsylvania State University research team documented the presence of a fracking-related solvent, 2-n-Butoxyethanol, in the drinking water from three homes in Bradford County, Pennsylvania, as part of an investigation of private drinking water wells near drilling and fracking operations that contained methane and foam. This finding represents the first fully documented case of a commonly used fracking chemical entering a drinking water source. “The most likely explanation of the incident is that stray natural gas and drilling or [hydrofracking] compounds were driven ~1-3 km along shallow to intermediate depth fractures to the aquifer used as a potable water source.”³⁶⁰ In an accompanying *New York Times* story, lead author Susan Brantley described the geology in northern Pennsylvania “as being similar to a layer cake with numerous layers that extend down thousands of feet to the Marcellus Shale. The vertical fractures are like knife cuts through the layers. They can extend deep underground, and can act like superhighways for escaped gas and liquids from drill wells to travel along, for distances greater than a mile away.”³⁶¹
- May 15, 2015 – A research team from the University of Colorado Boulder and California State Polytechnic Institute developed a model for identifying which fracking fluid chemicals are most likely to contaminate drinking water. Of 996 fracking fluid compounds known to be in use, researchers screened 659 of them for their ability to persist, migrate, and reach groundwater aquifers over a short time scale. Of the fifteen compounds so identified, two were commonly used in fracking operations: naphthalene and 2-butoxyethanol. Both are ingredients in surfactants and corrosion inhibitors. The authors noted that 2-butoxyethanol has been detected in drinking water in a heavily fracked area of Pennsylvania. Exposure to 2-butoxyethanol has been linked to birth defects in animals. Naphthalene is a possible human carcinogen that is toxic to red blood cells and contributes to kidney and liver damage. Researchers did not consider the impact of mixtures, interactions between contaminants, or chemical transformations during the fracking or flowback process and noted, “the need for data on the degradation of many

compounds used in fracturing fluids under conditions relevant for groundwater transport.”³⁶²

- May 7, 2015 – A survey of streams in Arkansas, led by the University of Central Arkansas, found alterations in macroinvertebrate communities to be related to drilling and fracking operations in the Fayetteville Shale. Fracking activity near streams was associated with greater sediment and more chlorophyll. “This study suggests that land disturbance from gas development affected stream communities.”³⁶³
- April 20, 2015 – A USGS team analyzed water brought to the surface during natural gas extraction at 13 fracked wells in northern Pennsylvania. They found large variability in the VOCs and microorganisms in the water samples from different wells. Organic chemical contaminants included benzene, toluene, and perchloroethylene, chloroform, and methylene chloride. The presence of microbes was associated with concentrations of benzene and acetate. Despite the addition of biocides during the fracking process, hydrogen sulfide-producing bacteria were present at culturable levels, along with methanogenic and fermenting bacteria. The source of these microorganisms was not determined. “Therefore, we cannot exclude the possibility that these microorganisms are native to the shale formation and reactivated by [hydrofracking] activities, as their physiology does not indicate a terrestrial surficial source.”³⁶⁴
- April 8, 2015 – A University of Colorado Boulder research team’s analysis of the organic chemicals found in liquid waste that flowed out of gas wells in Colorado after they had been fracked revealed the presence of many fracking fluid additives, including biocides, which are potentially harmful if they leak into groundwater. According to the authors, treatment of fracking wastewater must include aeration, precipitation, disinfection, a biological treatment to remove dissolved organic matter, and reverse osmosis desalination in order for it to be appropriate for non-fracking uses, such as crop irrigation.³⁶⁵
- March 18, 2015 – Using a new stream-based monitoring method, a team of scientists with USGS, Pennsylvania State University, and University of Utah found elevated levels of methane in groundwater discharging into a stream near drilling and fracking operations in Pennsylvania. In this same area, several private water wells contained high levels of methane as a result of gas migration near a gas well with a defective casing. The

monitoring technique used by the scientists allowed them to demonstrate that the source of the methane was shale gas from the Middle Devonian period, which is the kind of gas found in the Marcellus Shale.³⁶⁶ Researcher Susan Brantley said, “I found it compelling that using this new method for a reconnaissance of just 15 streams in Pennsylvania, we discovered one instance of natural gas entering the stream, perhaps from a nearby leaking shale gas well.”³⁶⁷

- March 12, 2015 – A team led by geologist Donald Siegel of Syracuse University found no relationship between methane levels in drinking water wells and proximity to oil or gas wells in a heavily fracked area of northeastern Pennsylvania.³⁶⁸ However, Siegel failed to reveal in his paper — as is required by the journal — that he had received industry funding from the Chesapeake Energy Corporation. Subsequently, the journal published a lengthy correction that revealed that Chesapeake had not only privately funded the lead author but had provided the baseline groundwater data set. A second author was revealed to be a former employee of Chesapeake, and another had worked as a consultant in the energy sector.³⁶⁹
- March 3, 2015 – A Duquesne University study of private drinking water wells in an intensely drilled southwestern Pennsylvania community compared pre-drill and post-drill data on water quality and found changes in water chemistry that coincided with the advent of drilling and fracking activities. Levels of chloride, iron, barium, strontium, and manganese were elevated. In some cases, concentrations exceeded health-based maximum contaminant levels. Methane was detected in most houses tested. Surveys of residents revealed widespread complaints about changes in water quality that began after drilling and fracking operations commenced. Violation records from the PA DEP uncovered possible pathways for water contamination. The researchers concluded that alterations of local hydrology caused by the injection of large volumes of hydraulic fracturing fluids may have mobilized contaminants left over from legacy oil, gas, and mining operations as well as opened pathways for the migration of fracking fluids themselves.³⁷⁰

Well water contamination in a rural community in southwestern Pennsylvania near unconventional shale gas extraction. *Journal of Environmental Science and Health, Part A: Toxic/Hazardous Substances and Environmental Engineering*, 50, 516-528. doi: 10.1080/10934529.2015.992684

- March 3, 2015 – A research team from Duquesne University reviewed the evidence for environmental impacts to air and water from activities related to shale gas extraction in Pennsylvania and explored potential mechanisms for contamination of air and water related to the drilling and fracking process itself. Among them: deformations of the shale bedrock caused by the injection of large volumes of fluid result in “pressure bulbs” that are translated through rock layers and can impact faults and fissures, so affecting groundwater.³⁷¹
- February 23, 2015 – The arrival of drilling and fracking activities coincided with an increase in salinity in a creek that drains public land in a semi-arid region of Wyoming, determined a USGS study. The dissolved minerals associated with the rise in salinity matched those found in native soil salts, suggesting that disturbance of naturally salt-rich soils by ongoing oil and gas activities, including pipeline, road, and well pad construction, was the culprit. “As [shale gas and oil] development continues to expand in semiarid lands worldwide, the potential for soil disturbance to increase stream salinity should be considered, particularly where soils host substantial quantities of native salts.”³⁷²
- February 14, 2015 – A review by a *Dickinson Press* news reporter of disposal well files and more than 2,090 mechanical integrity tests revealed that North Dakota frack waste injection wells were often leaky and that state regulators continued to allow fluid injection into wells with documented structural problems even though the wells did not meet EPA guidelines for wellbore integrity. Officials with the North Dakota Division of Oil and Gas said they had primary enforcement responsibilities and that EPA guidance did not apply to these wells. The investigation noted, “... a review of state and federal documents, as well as interviews with geologists, engineers, environmental policy experts and lawyers who have litigated under the Safe Drinking Water Act, suggests the agency is loosely interpreting guidance and protocols that are meant to maintain the multiple layers of protection that separate aquifers from the toxic saltwater.” *The Dickinson Press* is the daily newspaper for Stark County in southwest North Dakota.³⁷³
- February 11, 2015 – The *Los Angeles Times* analyzed self-reported testing results on fracking wastewater that California drillers were required to submit to the state. Samples of wastewater collected from 329 fracked oil wells found that virtually all—98 percent—contained benzene at levels that exceeded standards for permissible concentrations in drinking water. This finding likely underrepresents the extent of the problem, according

to the newspaper investigation, because many operators failed to comply with reporting requirements. The discovery that fracking wastewater is high in benzene is particularly alarming in light of the admission by the state of California that it had inadvertently allowed frack waste disposal directly into aquifers containing clean water that could potentially be used for drinking. Those wells are now the subject of federal and state review.³⁷⁴

- February 1, 2015 – An investigation of the chemical make-up of fracking fluid found that the compositions of these mixtures vary widely according to region and company, making the process of identifying individual compounds difficult. Classes of hydrocarbon-based chemicals include solvents, gels, biocides, scale inhibitors, friction reducers, and surfactants. Chemical analysis identified around 25 percent of the organic compounds that are believed to be present in fracking fluid and that are necessary to test for in identifying groundwater and drinking water contamination.³⁷⁵ Dr. Imma Ferrer, lead author, explained in a *Science Daily* article about her research that “[b]efore we can assess the environmental impact of the fluid, we have to know what to look for.”³⁷⁶
- January 30, 2015 – A USGS review of national water quality databases found that insufficient data exist to understand the impact of fracking on drinking water.³⁷⁷ In a media interview, lead author Zack Bowen said, “There are not enough data available to be able to assess the potential effects of oil and gas development over larger geographic areas.”³⁷⁸
- January 21, 2015 – A team of researchers from the USGS and Virginia Tech University established that petroleum-based hydrocarbons can break down underground in ways that promote the leaching of naturally occurring arsenic into groundwater. Arsenic is a known human carcinogen that causes bladder, lung, and skin cancer. Elevated levels of arsenic in drinking water represent a public health threat.³⁷⁹ Researchers found that arsenic concentrations in a hydrocarbon plume can reach 23 times the current drinking water

³⁷⁹ U.S. Geological Survey (2015, January. 26). Natural breakdown of petroleum underground can lace arsenic into groundwater. Retrieved from http://www.usgs.gov/newsroom/article.asp?ID=4110&from=rss&utm_source=dlvr.it&utm_medium=facebook#.VavGXIsqdyA

standard of 10 micrograms per liter. The authors of the study said that the metabolism of carbon-rich petroleum products by subterranean microbes is involved in a complex geochemical process that leads to mobilization of arsenic into aquifers.³⁸⁰

- January 14, 2015 – Researchers from Duke University, Dartmouth College, and Stanford University found high levels of iodide, bromide, and ammonium in samples of wastewater from fracking operations in both the Marcellus and Fayetteville Shales. These same chemicals were present when fracking wastewater was discharged into rivers and streams at three treatment sites in Pennsylvania and during an accidental spill in West Virginia. Iodide and bromide are known to create toxic disinfection byproducts when downstream water is subsequently chlorinated for drinking water. In water, ammonium can convert to ammonia, which is toxic to aquatic life. The authors noted that this is the first study to identify ammonium and iodide as widespread in fracking waste discharges.³⁸¹ In an interview with the *Pittsburgh Post-Gazette*, lead author Avner Vengosh said that the findings raise new concerns about the environmental and health impacts of wastewater from drilling and fracking operations.³⁸²
- November 27, 2014 – An interdisciplinary team of researchers found methane contamination in drinking water wells located in eight areas above the Marcellus Shale in Pennsylvania and the Barnett Shale in Texas, with evidence of declining water quality in the Barnett Shale area. By analyzing noble gases and their isotopes (helium, neon, argon), the investigators were able to isolate the origin of the fugitive methane in drinking water. The results implicate leaks through cement well casings as well as via naturally occurring cracks and fissures in the surrounding rock.³⁸³ In a related editorial, one of the study's authors, Robert Jackson, called on the EPA to reopen its aborted investigation into drinking water contamination in heavily fracked areas of Texas. Jackson also emphasized that methane migration through unseen cracks in the rock surrounding the wellbore “raises the interesting possibility that a drilling company could follow procedures — cementing and casing below the local aquifer — and still create a potential pathway for gas to migrate into drinking water.”³⁸⁴
- November 26, 2014 – A critical review of biocides in fracking fluid by a Colorado State team found that the fate of these chemicals underground is not known and their toxicity not well understood. While many biocides are short-lived, some may transform into more

toxic or persistent compounds. Among the most common chemical components of fracking fluid, biocides are used to inhibit the growth of deep-life microorganisms, including sulfate-reducing bacteria that contribute to corrosion of well casings and can form biofilms that prevent the upward flow of natural gas. Oxidizing biocides that are chlorine- or bromine-based can react with other fracking chemicals and may produce toxic halogenated byproducts. The authors noted biocides pose a unique risk for drinking water when fracking liquid waste is treated for discharge to surface water via sewage treatment plants. Sub-lethal concentrations may contribute to adaptation of surviving microorganisms and, hence, antibiotic resistance of pathogens. They cited particular concern over surface spills and well integrity issues associated with casing or cement failure.³⁸⁵

- November 3, 2014 – The West Virginia Department of Environmental Protection confirmed that three private drinking water wells were contaminated when Antero Resources mistakenly drilled into one of its own gas wells. Benzene, a human carcinogen, and toluene, a reproductive toxicant, were detected in the drinking water at concentrations four times the legal maximum limit. Additionally, a nearby abandoned gas well, a drinking water well, and an actively producing gas well were all pressurized as a result of the mishap and began exhibiting “artesian flow.”³⁸⁶
- October 22, 2014 – A follow-up to the August 2014 Environmental Integrity Project report describes an even greater potential public health threat from a loophole in the Safe Drinking Water Act, wherein companies are allowed to inject other petroleum products (beyond diesel) without a permit, and many of these non-diesel drilling fluids contain even higher concentrations of the same toxins found in diesel. The authors recommend that “EPA should revisit its guidance and broaden the categories of diesel products that require Safe Drinking Water Act permits before they can be injected into oil and gas wells.”³⁸⁷
- October 20, 2014 – While developing a technique to fingerprint and trace accidental releases of hydraulic fracturing fluids, researchers showed that liquid waste from shale gas fracking operations is chemically different than waste flowing out of conventional wells. The researchers hypothesized that the hydraulic fracturing process itself liberates elements from clay minerals in the shale formations, including boron and lithium, which then enter the liquid waste.³⁸⁸

- October 15, 2014 – Four thousand gallons of liquid fracking waste dumped into Waynesburg sewer system was discovered by sewage treatment plant workers in Greene County, Pennsylvania. The Department of Environmental Protection surmised that “someone removed a manhole cover in a remote location and dumped the fluid.” The treatment plant discharges into a creek that feeds the Monongahela River, which provides drinking water to more than 800,000 people.³⁸⁹
- October 6, 2014 – A state investigation that found no fracking-related water contamination in a drinking water well in Pennsylvania’s Washington County was invalidated by testimony presented to the state Environmental Hearing Board. Not all contaminants that were present in the water were reported, and the investigation relied on obsolete testing methods. More sophisticated testing revealed the presence of several chemical contaminants in the well water. The well is located 2,800 feet down gradient from a drilling site and fracking waste pit where multiple spills and leaks more than four years earlier had contaminated two springs.³⁹⁰
- September 23, 2014 – In a two-part audit of records, the GAO found that the EPA is failing to protect U.S. drinking water sources from fracking-related activities such as waste disposal via injection wells. Nationwide, 172,000 injection wells accept fracking waste; some are known to have contaminated drinking water. And yet, both short-term and long-term monitoring is lax, and record-keeping varies widely from state to state. The EPA neither mandates nor recommends a fixed list of chemicals for monitoring on the grounds that “injection fluids can vary widely in composition and contain different naturally occurring chemicals and fluids used in oil and gas production depending on the source of the injection fluid.”³⁹¹ Disposal of oil and gas waste via injection wells is, in fact, subject to regulation under the Safe Drinking Water Act, but, in practice, no one knows exactly what the waste contains, and regulations are deficient. In the United States, at least two billion gallons of fluids are injected into the ground *each day* to enable oil and gas extraction via fracking or to dispose of liquid waste from fracking operations.^{392, 393}
- September 18, 2014 – Range Resources was fined a record \$4.5 million by the Pennsylvania Department of Environmental Protection for contaminating groundwater.

The culprits were six leaking pits in Washington County that each held millions of gallons of fracking wastewater.³⁹⁴

- September 12, 2014 – A Pennsylvania State ecosystems scientist, together with USGS scientists, reviewed the current knowledge of the effects of fracking and its associated operations on terrestrial and aquatic ecosystems in 20 shale plays in the U.S. Findings of species and habitats at highest risk include (in addition to land-based examples) vernal pond inhabitants and stream biota. The research builds on previous reviews identifying “three main potential stressors to surface waters: changes in water quantity (hydrology), sedimentation, and water quality.” Researchers determined that there are no published data specifically on the effects of fracking on forest-dwelling amphibians, but “many species breed in vernal ponds which are negatively affected by changes in water quantity and quality and direct disturbance. Many amphibians are also highly sensitive to road salts.” Given that the U.S. EPA recently found 55 percent of all rivers and streams to be in poor condition, these researchers warned, “Large-scale development of shale resources might increase these percentages.” They expressed concern for the native range of brook trout by the cumulative effects of shale development, especially in Pennsylvania.³⁹⁵
- September 9, 2014 – A research team from Stanford and Duke Universities discovered that fracking wastewater processed by sewage treatment plants contributes to the formation of carcinogenic chemical byproducts. These raise public health risks when downstream surface water is used for drinking. Even when fracking wastewater was diluted by a factor of 10,000, the bromides and iodides in the waste reacted with organic matter to create highly toxic halogenated compounds—at troublingly high concentrations. These toxic compounds are not filterable by municipal wastewater treatment plants. Halogenated disinfection byproducts in drinking water are linked to both colon and bladder cancers.³⁹⁶
- August 29, 2014 – A review of Pennsylvania Department of Environmental Protection files on fracking-related damage to drinking water—which are kept on paper and stored in regional offices—revealed that 243 private water supplies in 22 counties had been contaminated or had lost flow and dried up as a result of nearby drilling and fracking operations in the past seven years. Pollutants included methane, metals, and salts as well as carbon-based compounds (ethylene glycol and 2-butoxyethanol) that are known to be constituents of fracking fluid. As reported by the *Pittsburgh Post-Gazette*, this tally—which came as a response to multiple lawsuits and open-records requests by media

sources—was the first time the agency “explicitly linked a drilling operation to the presence of industrial chemicals in drinking water.”^{397, 398}

- August 13, 2014 – Over the last decade, drilling companies have repeatedly claimed they are no longer using diesel fuel in fracking, although a 2011 investigation by U.S. House Democrats concluded otherwise. The Environmental Integrity Project examined disclosure data submitted to FracFocus and identified at least 351 wells in 12 states that have been fracked over the last four years with one or more of the five prohibited products identified as diesel. EIP researchers also discovered numerous fracking fluids with high diesel content for sale online, including over a dozen products sold by Halliburton and advertised as additives, friction reducers, emulsifiers, etc.³⁹⁹
- August 13, 2014 – An international team of researchers found high levels of carbon-based compounds in liquid fracking waste. These impurities can react with chlorine and bromine to create toxic byproducts. This study suggests that chemical treatment of liquid fracking waste will magnify its toxic potency, as will reusing and recycling it.⁴⁰⁰ The European Commission subsequently published a summary of these findings.⁴⁰¹
- August 13, 2014 – A team from Lawrence Berkeley National Laboratory reported that scientific efforts to understand the hazards of fracking continue to be hampered by industry secrecy. A comprehensive examination of the chemical formulations of fracking fluid—whose precise ingredients are protected as proprietary business information—revealed that no publicly available toxicity or physical chemical information was available for one-third of all the fracking chemicals surveyed. Another ten percent of chemicals, including biocides and corrosion inhibitors, were known to be toxic to mammals.^{402, 403}

- August 12, 2014 – A Stanford University research team working in the Pavillion gas basin in Wyoming documented that fracking in shallow layers of bedrock, including those that serve as drinking water aquifers, is not uncommon. This finding overturns the industry claim that oil and gas deposits targeted by fracking operations are located at much greater depths than underground drinking water sources and are isolated from them by hundreds of feet of impermeable rock. Because it is exempt from provisions of the Safe Drinking Water Act, fracking in drinking water aquifers is not prohibited by law.⁴⁰⁴
- August 3, 2014 – An investigation by the *Pittsburgh Post-Gazette* found that half of all fracking-related spills that resulted in violations and fines were not discovered by the gas companies themselves, even though Pennsylvania state law requires them to pro-actively seek and report such incidents. The newspaper’s analysis of hundreds of thousands of state and company documents showed that self-regulation in the gas fields is a failure. One-third of all spills were discovered by state inspectors, while one-sixth were found by residents. Likely, much contamination is entirely undetected and unreported.⁴⁰⁵
- July 21, 2014 – An investigation by the *Columbus Dispatch* showed that Halliburton delayed disclosure to federal and state EPA agencies of the full list of chemicals that spilled into a creek following a fire on one of its well pad in Monroe County, Ohio. Although the creek is an important supply of drinking water for downstream communities and the spill precipitated a mass die-off of fish and other aquatic wildlife, five full days passed before EPA officials were provided a full inventory of chemicals used at Halliburton’s operation. As a result, the public was denied knowledge of potential chemical exposures.⁴⁰⁶
- July 17, 2014 – A team of environmental scientists, biologists, and engineers, from institutions including the University of Michigan and McGill University, assessed the current state of understanding of the impact fracking and its associated activities have on the ecological health of surface waters. Though various approaches such as geographic information systems and site monitoring provide insights into potential risks to aquatic ecosystems, the authors concluded that inadequate data currently exist. They identified possible outcomes such as, “erosion and sedimentation, increased risk to aquatic ecosystems from chemical spills or runoff, habitat fragmentation, loss of stream riparian

zones, altered biogeochemical cycling, and reduction of available surface and hyporheic water volumes because of withdrawal-induced lowering of local groundwater levels.”⁴⁰⁷

- July 7, 2014 – California Department of Gas, Oil, and Geothermal Resources ordered seven energy companies to stop injecting liquid fracking waste into aquifers. The ongoing drought that has compelled farmers to supplement irrigation with water drawn from groundwater sources prompted state officials to look at the status of aquifers previously considered too deep for use or too poor in quality. They discovered that at least seven injection wells were very likely pumping liquid fracking waste into protected groundwater supplies rather than aquifers that had been sacrificed for the purpose of waste disposal. Across the United States, more than 1000 aquifers are exempt from any type of pollution protection at all, and many of these are in California, according to a related *ProPublica* investigation.⁴⁰⁸
- June 25, 2014 – A study by Cornell University researchers found that fracking fluid and fracking wastewater mobilized previously deposited chemical contaminants in soil particles in ways that could potentially exacerbate the impacts of fracking fluid spills or leaks. The research team concluded that, by interfering with the ability of soil to bond to and sequester pollutants such as heavy metals, fracking fluids may release from soils an additional repository of contaminants that could migrate into groundwater.⁴⁰⁹
- June 23, 2014 – Building on earlier findings that water samples collected from sites with confirmed fracking spills in Garfield County, Colorado exhibited moderate to high levels of estrogen and androgen-disrupting activity, a University of Missouri team extended their investigation to other types of hormonal effects. As reported at a joint meeting of the International Society of Endocrinology and the Endocrine Society, their research documented that commonly used fracking chemicals can also block the receptors for thyroid hormone, progesterone, and glucocorticoids (a family of hormones involved in both fertility and immune functioning). Of 24 fracking chemicals tested, all 24 interfered with the activity of one or more important hormone receptors. There is no known safe level of exposure to hormone-disrupting chemicals.⁴¹⁰
- May 11, 2014 – According to the GAO, the federal government is failing to inspect thousands of oil and gas wells located on public land, including those that pose special

risks of water contamination or other environmental damage. An investigation by the Associated Press found that the Bureau of Land Management “had failed to conduct inspections on more than 2,100 of the 3,702 wells that it had specified as ‘high priority’ and drilled from 2009 through 2012. The agency considers a well ‘high priority’ based on a greater need to protect against possible water contamination and other environmental safety issues.”⁴¹¹

- March 25, 2014 – An industry-funded study of oil and gas well integrity found that more than six percent of wells in a major shale exploration region in Pennsylvania showed evidence of leaking and conceded that this number is likely an underestimate. Researchers concluded that the percentage of wells with some form of well barrier or integrity failure is highly variable and could be as high as 75 percent. A separate analysis in the same study found 85 examples of cement or casing failures in Pennsylvania wells monitored between 2008 and 2011.⁴¹²
- March 7, 2014 – In a comprehensive evaluation, Duke University scientists and colleagues reviewed the state of knowledge on possible effects of shale gas and hydraulic fracturing on water resources in the United States and concluded, “Analysis of published data (through January 2014) reveals evidence for stray gas contamination, surface water impacts in areas of intensive shale gas development, and the accumulation of radium isotopes in some disposal and spill sites.”⁴¹³
- February 19, 2014 – A Pennsylvania court found a gas corporation guilty of contaminating a woman’s drinking water well in Bradford County. Methane levels after fracking were 1,300-2,000 times higher than baseline, according to the court brief. Iron levels and turbidity had also increased. The brief stated, “In short, Jacqueline Place lived for ten months deprived totally of the use of her well, and even after its ‘restoration,’ has been burdened with a water supply with chronic contamination, requiring constant vigilance and ongoing monitoring.”⁴¹⁴
- January 16, 2014 – Data from the Colorado Oil and Gas Conservation Commission showed that fracking-related chemical spills in Colorado exceed an average rate of one spill per day. Of the 495 chemical spills that occurred in that state over a one-year period of time, nearly a quarter impacted ground or surface water. Sixty-three of the spills spread within 1,500 feet of pigs, sheep, and cows; 225 spread within 1,500 feet of

buildings.⁴¹⁵

- January 10, 2014 – Duke University water tests revealed ongoing water contamination in Parker County, Texas, providing evidence that the EPA had prematurely ended its prior investigation into the water contamination.⁴¹⁶ A letter sent to the EPA from more than 200 environmental organizations called on the agency to re-open its investigation.⁴¹⁷
- January 5, 2014 – An Associated Press investigation into drinking water contamination from fracking in four states—Pennsylvania, Ohio, West Virginia, and Texas—found many cases of confirmed water contamination and hundreds more complaints. The Associated Press noted that their analysis “casts doubt on industry view that it rarely happens.”⁴¹⁸
- December 24, 2013 – A report from the EPA Inspector General concluded that evidence of fracking-related water contamination in Parker County, Texas was sound and faulted the EPA for prematurely ending its investigation there, relying on faulty water testing data from the gas industry in doing so, and failure to intervene when affected residents’ drinking water remained unsafe.⁴¹⁹ As reported by *Business Insider*, “The EPA Screwed Up When It Dropped This Fracking Investigation.”⁴²⁰
- December 16, 2013 – Lead by Susan Nagel of the University of Missouri School of Medicine, researchers documented endocrine-disrupting properties in chemicals commonly used as ingredients of fracking fluid and found similar endocrine-disrupting activity in groundwater and surface water samples collected near drilling and fracking sites in Garfield County, Colorado. Endocrine disruptors are chemicals that interfere with the activity of hormones in the body and, at very low concentrations, can raise the risk of reproductive, metabolic, and neurological disorders, especially when exposures occur in early life.^{421, 422, 423}

- December 7, 2013 – Reporting on the second gas leak at a single gas well in one month, the Fort Worth *Star-Telegram* uncovered another inherent risk of fracking for groundwater contamination: Silica sand, which is used as an ingredient in fracking fluid for its ability to prop open the shale fractures, can damage steel pipes as it flows back up the well along with the gas. According to Dan Hill, head of the petroleum engineering department at Texas A&M University, new wells are the most susceptible to sand erosion because “the amount of sand and gas rushing through valves and flow lines is at its greatest when a well first goes into production.”⁴²⁴
- November 28, 2013 – An Associated Press investigation uncovered nearly 300 oil pipeline spills in North Dakota in the previous ten months, all with no public notification. These were among some 750 “oil field incidents” that had occurred in the state over the same time period, also without public notification. Until the AP inquiry, industry and state officials had kept quiet about one particular “massive spill” that had been accidentally discovered by a wheat farmer. Even small spills can contaminate water sources permanently and take cropland out of production.⁴²⁵
- November 26, 2013 – A USGS report found serious impacts of fracking on watersheds and water quality throughout the Appalachian Basin, as well as issues with radiation and seismic events. As noted in the report, the knowledge of how extraction affects water resources has not kept pace with the technology.^{426, 427} Meanwhile, clean fresh water is becoming an increasingly scant resource. A report prepared for the U.S. State Department forecasts a serious freshwater shortage by 2030, with global demand exceeding supply by 40 percent.⁴²⁸
- November 22, 2013 – A USGS study of pollution from oil production in North Dakota, where horizontal drilling and hydraulic fracturing are heavily used, identified two potential plumes of groundwater contamination covering 12 square miles. The cause was traced to a casing failure in a wastewater disposal well. Drilling companies had incorrectly assumed that, once injected underground, the wastewater would remain contained. According to *EnergyWire*, the development of the Bakken oil formation is

“leaving behind an imprint on the land as distinct as the ones left by the receding ice sheets of the ice age.”⁴²⁹

- September 10, 2013 – Pennsylvania Attorney General Kathleen Kane filed criminal charges against Exxon Mobil Corporation’s subsidiary, XTO Energy Corporation, for a spill of 50,000 gallons of toxic drilling wastewater in 2010 that contaminated a spring and a tributary of the Susquehanna River. In July, XTO settled civil charges for the incident without admitting liability by agreeing to pay a \$100,000 fine and improve its wastewater management.⁴³⁰
- September 10, 2013 – Out of concern for risks posed to drinking water in the nation’s capital, George Hawkins, General Manager of DC Water, Washington, DC’s local water provider, called for a prohibition on horizontal drilling and hydraulic fracturing in the George Washington National Forest until the process can be proven safe.⁴³¹ The Potomac River is the source of the District’s water supply and has its headwaters in the George Washington National Forest, which sits atop the Marcellus Shale. The general managers of Fairfax Water, provider of drinking water for Fairfax County, Virginia, and the U.S. Army Corps of Engineers have called for a similar prohibition.⁴³²
- September 3, 2013 – The North Dakota Department of Mineral Resources voiced concern about an increasing number of fracking well blowouts (23 incidents in the past year) that result in spills and public safety threats.⁴³³
- August 28, 2013 – A joint USGS and U.S. Fish and Wildlife Service study documented a causal link between a fracking wastewater spill and the widespread death of fish in the Acorn Fork, a creek in Kentucky.⁴³⁴
- July 25, 2013 – A University of Texas at Arlington study of drinking water found elevated levels of arsenic and other heavy metals in some samples from private drinking

water wells located within five kilometers of active natural gas wells in the Barnett Shale.⁴³⁵

- July 3, 2013 – *ProPublica* reported that the EPA was wrong to have halted its investigation of water contamination in Wyoming, Texas and Pennsylvania—where high levels of benzene, methane, arsenic, oil, methane, copper, vanadium, and other chemicals associated with fracking operations have been documented.⁴³⁶ Although numerous organizations and health professionals around the country have since called on the agency to resume its investigation, no action has been taken.
- June 6, 2013 – Reviewing hundreds of regulatory and legal filings, *Bloomberg News* reported that drillers have offered out-of-court cash settlements and property buyouts to homeowners who claim that fracking ruined their water. These agreements typically come with gag orders and sealed records. This strategy, the investigation noted, allows the industry to continue claiming that no cases of water contamination due to fracking have ever been confirmed, impedes public health research, and shields data from regulators, policy makers, and the new media.⁴³⁷ The EPA also long ago noted how non-disclosure agreements between oil and gas operators and landowners challenge scientific progress and keep examples of drilling harm secret from the public. In a 1987 report, the EPA wrote, “In some cases, even the records of well-publicized damage incidents are almost entirely unavailable for review. In addition to concealing the nature and size of any settlement entered into between the parties, impoundment curtails access to scientific and administrative documentation of the incident.”⁴³⁸
- June 3, 2013 – A study by Duke University researchers linked fracking with elevated levels of methane, ethane, and propane in nearby groundwater.⁴³⁹ Published in *Proceedings of the National Academy of Sciences*, the study included results from 141 northeastern Pennsylvania water wells. Methane levels were, on average, six times higher in drinking water wells closer to drilling sites when compared with those farther away, while ethane was 23 times higher.⁴⁴⁰

- May 19, 2013 – In Pennsylvania, the *Scranton Times-Tribune* released details of an investigation that revealed at least 161 cases of water contamination from fracking between 2008 and the fall of 2012, according to state Department of Environmental Protection records.⁴⁴¹
- April 2013 – Researchers analyzing publicly available Colorado data found 77 surface spills impacting groundwater in Weld County alone. Samples of these spills often exceeded drinking water maximum contaminant levels (MCLs) for benzene, toluene, ethylbenzene and xylene; for benzene, a known carcinogen, 90 percent of the samples exceeded the legal limit.⁴⁴²
- March 4, 2013 – Researchers at the University of Pittsburgh Graduate School of Public Health analyzed samples of gas drilling wastewater discharged to surface water through wastewater treatment plants. Barium, strontium, bromides, chlorides, and benzene all exceeded levels known to cause human health impacts.⁴⁴³
- December 9, 2012 – State data in Colorado showed more than 350 instances of groundwater contamination resulting from more than 2,000 spills from oil and gas operations over the past five years. Further, as the *Denver Post* reported, “Contamination of groundwater—along with air emissions, truck traffic and changed landscapes—has spurred public concerns about drilling along Colorado’s Front Range.”⁴⁴⁴
- May 4, 2012 – A report for the Canadian Government, released under the Access to Information Act, reviewed the process, the regulatory framework globally, and the potential health hazards related to shale gas extraction. Additionally, the report evaluated mechanisms for potential impacts and summarized the data knowledge and data gaps. Regarding water contamination, the report determined, “Although quantitative data are lacking, the qualitative data available indicate that potential contamination of water related to the shale gas industry may present hazard to the public health, especially for local population.” Regarding air contamination: “air emissions related to the shale gas industry present health hazards since the air pollutants originating from the vehicles and engines fuelled by diesel are toxic to the respiratory and cardiovascular systems and can cause premature mortality, volatile organic compounds have been associated to neurotoxicity and some of these compounds (e.g. benzene) as well as NORMs are known or possible human carcinogens.” The report concluded, “Any step of shale gas

exploration/exploitation may represent a potential source of drinking water and air contamination; Hydraulic fracturing and wastewater disposal were identified as the main potential sources of risk.”⁴⁴⁵

- May 2012 – A report by researchers at Natural Resources Defense Council and Carnegie Mellon University found that the options available for dealing with fracking wastewater are inadequate to protect public health and the environment, resulting in increasing quantities of toxic wastewater as an ongoing problem without a good solution.⁴⁴⁶
- January 11, 2012 – The USGS reported that the Marcellus Shale is already highly fractured and that numerous fissures naturally occurring within the formation could potentially provide pathways for contaminants to migrate vertically into water supplies.⁴⁴⁷
- October 25, 2011 – After receiving new information from two companies, members of Congress updated their findings to show that “between 2005 and 2009, oil and gas service companies injected 32.7 million gallons of diesel fuel or hydraulic fracturing fluids containing diesel fuel in wells in 20 states.”⁴⁴⁸
- October 17, 2011 – Thomas P. Jacobus, General Manager of the U.S. Army Corps of Engineers’ Washington Aqueduct, called for a prohibition on horizontal hydraulic fracturing in the George Washington National Forest because of concern that fracking poses risks to drinking water. The Washington Aqueduct—which provides drinking water to Washington, DC, Arlington County, Virginia, and Falls Church, Virginia—is supplied by the Potomac River, which has its headwaters in the George Washington National Forest that sits atop the Marcellus Shale. Jacobus said, “Enough study on the technique [hydraulic fracturing] has been published to give us great cause for concern about the potential for degradation of the quality of our raw water supply....”⁴⁴⁹
- October 11, 2011 – Charles M. Murray, General Manager of Fairfax Water, called for a prohibition on horizontal hydraulic fracturing in the George Washington National Forest. “Natural gas development activities have the potential to impact the quantity and quality

⁴⁴⁵ Louis, S. (2012, May 4). Potential health hazards from shale gas exploration and exploitation—Drinking water and ambient air. Presented to Health Canada by SANEXEN Environmental Services; 0/Ref.: RA11-410. Document released under the (Canadian) Access to Information Act.

of Fairfax Water’s source water,” Murray wrote. “Downstream water users and consumers will bear the economic burden if drinking water sources are contaminated or the quality of our source water supply is degraded.”⁴⁵⁰ Fairfax Water provides drinking water for Fairfax County in Virginia.

- September 7, 2011 – In its draft Supplemental Generic Environmental Impact Statement (SGEIS), the New York State Department of Environmental Conservation (NYS DEC) acknowledged that “there is questionable available capacity”⁴⁵¹ for New York’s public sewage treatment plants to accept drilling wastewater, yet the agency said that it would allow those facilities to accept such waste if the plants meet permitting conditions.⁴⁵² The NYS DEC proposed underground injection as one alternative to sewage treatment procession of fracking waste. Although it is a common method of disposal for fracking wastewater,⁴⁵³ the last significant government study of pollution risks from oil and gas wastewater injection wells occurred in 1989 and found multiple cases of costly groundwater contamination.⁴⁵⁴ In subsequent years, studies have continued to link underground injection of drilling wastewater to pollution as well as earthquakes.⁴⁵⁵
- September 2011 – A team led by Theo Colburn of the Endocrine Disruptor Exchange found that 25 percent of chemicals known to be used in fracking fluids are implicated in cancer, 37 percent could disrupt the endocrine system, and 40-50 percent could cause nervous, immune and cardiovascular system problems. The research team also found that more than 75 percent could affect the skin, eyes, and respiratory system, resulting in various problems such as skin and eye irritation or flu-like symptoms.⁴⁵⁶
- August 4, 2011 – As reported by the *New York Times*, the EPA had alerted Congress in 1987 about a case of water contamination caused by fracking. Its report documented that

a shale gas well hydraulically fractured at a depth of more than 4,200 feet contaminated a water supply only 400 feet from the surface.^{457, 458, 459}

- May 17, 2011 – The state of Pennsylvania fined Chesapeake Energy Corporation \$900,000 for an incident in which improper cementing and casing in one of the company’s gas wells allowed methane to migrate underground and contaminate 16 private drinking water wells in Bradford County.⁴⁶⁰
- May 17, 2011 – A Duke University study documented “systematic evidence for methane contamination of drinking water associated with shale gas extraction.”⁴⁶¹ The study showed that methane levels were 17 times higher in water wells near drilling sites than in water wells in areas without active drilling.⁴⁶²
- April 22, 2011 – Describing one of many blowouts, the Associated Press reported on a shale gas well in Canton, Pennsylvania that spewed thousands of gallons of chemical-laced water on farmland and into a stream for two consecutive days before being brought under control.⁴⁶³
- April 18, 2011 – As part of a year-long investigation into hydraulic fracturing and its potential impact on water quality, U.S. Representatives Henry Waxman (D-Calif.), Edward Markey (D-Mass.) and Diana DeGette (D-Colo.) released the second of two reports issued in 2011. Their analysis of hydraulic fracturing fluids used by the 14 leading oil and natural gas service companies between 2005 and 2009 found, among other things, that the companies used more than 650 different products that contained chemicals that are known or possible human carcinogens, regulated under the Safe Drinking Water Act, or listed as hazardous air pollutants under the Clean Air Act. The report also showed that “between 2005 and 2009, the companies used 94 million gallons of 279 products that contained at least one chemical or component that the manufacturers deemed proprietary or a trade secret ... in most cases the companies stated that they did not have access to proprietary information about products they purchased ‘off the shelf’ from chemical suppliers. In these cases, the companies are injecting fluids containing

chemicals that they themselves cannot identify.”⁴⁶⁴ These findings were reported in the *New York Times*.⁴⁶⁵

- January 2011 – A team of scientists led by a University of Central Arkansas researcher called attention to the threat posed to surface waters by rapidly expanding shale gas development, noting a lack of data collection accompanying the rush to drill. “Gas wells are often close to surface waters that could be impacted by elevated sediment runoff from pipelines and roads, alteration of stream flow as a result of water extraction, and contamination from introduced chemicals or the resulting wastewater.”⁴⁶⁶
- January 31, 2011 – As part of a year-long investigation into hydraulic fracturing and its potential impact on water quality, U.S. Representatives Henry Waxman (D-Calif.), Edward Markey (D-Mass.) and Diana DeGette (D-Colo.) reported that “between 2005 and 2009, oil and gas service companies injected 32.2 million gallons of diesel fuel or hydraulic fracturing fluids containing diesel fuel in wells in 19 states.” Furthermore, revealing apparent widespread violation of the Safe Drinking Water Act, the investigation found that no oil and gas service companies had sought—and no state or federal regulators had issued—permits for the use of diesel fuel in hydraulic fracturing.⁴⁶⁷
- April 29, 2010 – In 2010, the Colorado Oil and Gas Conservation Commission fined Occidental Petroleum Corporation (OXY) USA a record \$390,000 for an incident of pollution, discovered in 2008, when its drilling wastes leaked through an unlined pit, contaminated two springs with benzene, and polluted other nearby water sources. In addition, the regulators separately fined OXY USA \$257,400 for a nearby case of pollution, also discovered in 2008, in which a torn liner in a pit caused drilling waste fluids to leak out and contaminate two springs with benzene.⁴⁶⁸
- June 5, 2009 – A leaking pipe carrying fracking waste in Washington County, Pennsylvania, polluted a tributary of Cross Creek Lake, killing fish, salamanders, crayfish, and aquatic insect life in approximately three-quarters of a mile of the stream.⁴⁶⁹

Inherent engineering problems that worsen with time

Studies show that many oil and gas wells leak, allowing for the migration of natural gas and potentially other substances into groundwater and/or the atmosphere. About five percent of wells leak immediately, 50 percent leak after 15 years, and 60 percent leak after 30 years. The act of fracking itself can redistribute stress and create underground pathways for fluid migration, which, in turn, can communicate with pathways caused by deterioration of cement in aging well casings, leading to both groundwater contamination and atmospheric emissions.

The problem of leaking wells, first identified by industry, has no known solution. Data from Pennsylvania's Department of Environmental Protection (DEP) agree, showing over nine percent of shale gas wells drilled in the state's northeastern counties leaking within the first five years. Leaks pose serious risks, including potential loss of life or property from explosions and migration of gas and other harmful chemicals into drinking water supplies. Methane leaking into aquifers can, under some conditions, be transformed by bacteria into hydrogen sulfide and other poisonous byproducts. Microbes from deep shale formations can likewise generate sulfides contributing, over time, to corrosion of pipes and casings.

There is no evidence to suggest that the problem of cement and well casing impairment is abating. Industry has no solution for rectifying the chronic problem of well casing/cement failures and resulting leakage. Plugging old, inactive wells is an imperfect solution because, as research shows, the cement plugs themselves degrade over time and because many wells leak from outside the well casing.

- April 19, 2018 – As part of a major review, a University of Aberdeen team of researchers assessed the various underground pathways by which fracking creates methane leaks and concluded that aging well casings are a leading cause of methane leaks from drilling and fracking operations. While the intersection of fracture propagation with naturally present geological faults in the subsurface is another potential route for methane leakage, the more important route is the intersection of fracture propagation with other wells with old cement. “The major sources of methane leakage related to shale gas activities are the intersections of hydraulic fractures with abandoned oil and gas wells which have a reduced mechanical well integrity due to cement degradation. As a result, the stress redistributions caused by hydraulic fracturing and the deterioration of cement in abandoned wells with age allow migration pathways to be created easily, leading to both groundwater contamination and atmospheric emissions.” Plugging wells is an imperfect solution because the cement commonly used for this process itself degrades with time, especially in the presence of carbon dioxide. “No concrete method [has been] established for the methane leakage mitigation from shale gas wells.”⁴⁷⁵

- November 23, 2017 – An investigative journalist from *The Tyee* in Vancouver obtained a copy of a 2013 report from British Columbia’s Oil and Gas Commission warning about hundreds of uncontrolled methane leaks from shale gas wells located in the northern Rocky Mountain range near Fort Nelson. The commission’s report, never shared with the public or with elected officials, remained an internal document until it was uncovered by the newspaper. Cornell University engineer Anthony Ingraffea, quoted in the story, said the report’s findings served as another confirmation that wells leak badly and inevitably over time. “What do they expect from underground operations such as these, total obedience to design intent? Why are operators and regulators around the world seemingly surprised when things go wrong underground, and in so many ways, and so often?” Ingraffea said.^{476, 477}
- July 5, 2017 – A team of researchers led by microbiologists from Ohio State University investigated bacteria from hydraulically fractured shale by sampling fracking wastewater from a well drilled in the Utica shale. The dominant microorganism was a bacterium that generates sulfides, which can contribute to corrosion of well casings. “The impact of microbial metabolism within these environments is poorly understood. . . . These findings emphasize the potential detrimental effects that could arise from thiosulfate-reducing microorganisms in hydraulically fractured shales, which are undetected by current industry-wide corrosion diagnostics.”⁴⁷⁸
- April 1, 2017 – The rapid depletion of fracked wells requires drilling ever more wells to keep up with production. As time goes by, wells become more densely packed into a drilling section. Decreasing distances between wells increases the risk of inter-well communication, which occurs when the pumping of fracking fluid into one well affects a nearby well. According to an analysis in the *Journal of Petroleum Technology*, these so called “frack hits” are unpredictable, uncontrolled, and can be violent, damaging tubing, casings, and well integrity. In some cases, frack hits involve blowouts of fracking fluid. The industry has no solution for this increasingly common problem.⁴⁷⁹ Indeed, as a sequel report describes, operators use frack hits as a tool for revealing how tightly wells can be spaced in a drilling section to maximize extraction—even while acknowledging inherent safety risks. A drilling section with no frack hits at all is presumed to lack sufficient well density for optimal “economic recovery.”⁴⁸⁰

(CCST) documented cases of well failures triggered by underground movements that caused well casings to shear. Sheared well casings can allow gas and fluids from the fracking zone to migrate to overlying aquifers. The CCST team identified several mechanisms by which casing shears can occur in California as oil wells age: surface subsidence, heaving, reservoir compaction, and earthquakes. Prolonged drought can also damage the integrity of well casings: as groundwater levels fall, landforms can sink and contribute to casing shear.⁴⁸¹

- June 30, 2015 – According to the New York State Department of Environmental Conservation (NYS DEC) Findings Statement, “there is a risk that well integrity can fail, especially over time, and questions have arisen about whether high-volume hydraulic fracturing can cause seismic changes which could potentially result in fracturing fluid migration through abandoned wells or existing fissures and faults. Thus, high-volume hydraulic fracturing could result in significant adverse impacts to water resources from well construction and fracturing fluid migration.”⁴⁸²
- June 4, 2015 – As part of a draft assessment of fracking’s impact on drinking water, the U.S. Environmental Protection Agency (EPA) examined cases of water contamination across the United States and concluded that “construction issues, sustained casing pressure, and the presence of natural faults and fractures can work together to create pathways for fluids to migrate toward drinking water resources.” Fracking older wells poses additional risks, the draft study notes, because aging itself “can contribute to casing degradation, which can be accelerated by exposure to corrosive chemicals, such as hydrogen sulfide, carbonic acid, and brines” and because many older wells were never designed to withstand the high pressures and stress of fracking operations. The EPA estimates that 6 percent of the 23,000 U.S. oil and gas wells (= 1,380 wells) first fracked in 2009 or 2010 were drilled more than ten years earlier.⁴⁸³
- December 2, 2014 – Problems with structural integrity have been documented in a well at the only hydraulically fractured site in the United Kingdom. Email messages obtained under freedom of information laws reveal that problems with wellbore integrity emerged in April of 2014 and attempts were made to remediate the problem, although nothing was reported at that time to regulators. The drilling company, Cuadrilla Resources, continues to deny that any problems exist with the well, emphasizing that “no leak of fluids” occurred and that “the issue” was resolved during the abandonment process. Cuadrilla

had previously been reprimanded for failing to disclose a more minor deformation in the well casing. The well was abandoned at the end of last year, following two earthquakes in 2011, which scientists determined to have been caused by fracking at the site.⁴⁸⁴

- August 11, 2014 – Researchers affiliated with multiple universities and with the Los Alamos National Laboratory summarized recent field observations of wellbore-integrity failure, concluding that, because at least some well failures are not identified, reported barrier failure rates of 1-10 percent of wells and reported rates of groundwater contamination of 0.01-0.1 percent of wells constitute a “lower bound” for possible environmental problems. Citing hydraulic fracturing, as well as temperature and pressure changes, as operations that can induce pathways for leaks, the authors point out that few studies have considered the very-long-term fate (“>50 years”) of wellbore systems. They include “whether unconventional resource development alters the frequency of well integrity failures” as a critical topic for future research.⁴⁸⁵
- July 30, 2014 – Based on records obtained from Pennsylvania’s DEP, Scranton’s *Times-Tribune* reported that five natural gas wells in Bradford County have leaked methane for years because of persistent casing and cement problems. In the most recent violation, a PA-DEP inspector found combustible gas flowing through vents connected to the cement between layers of pipe. The agency issued a notice of violation for each well, saying combustible gas outside the well’s surface casing violates state regulations. Each of the wells has four layers of steel casing, but nothing prevents leaking (stray) methane from flowing into the atmosphere. No evidence of water contamination has yet been seen. None of the wells have produced any gas for sale.⁴⁸⁶
- June 30, 2014 – A study published in *Proceedings of the National Academy of Sciences* by a Cornell University research team projected that over 40 percent of shale gas wells in Northeastern Pennsylvania will leak methane into groundwater or the atmosphere over time. Analyzing more than 75,000 state inspections of more than 41,000 oil and gas wells in Pennsylvania since 2000, the researchers identified high occurrences of casing and cement impairments inside and outside the wells. A comparative analysis showed that newer, unconventional (horizontally fracked) shale gas wells were leaking at six times the rate of conventional (vertical) wells drilled over the same time period. The leak rate for unconventional wells drilled after 2009 was at least six percent, and rising with time. In the state’s northeastern counties between 2000 and 2012, over nine percent of shale gas wells drilled leaked within the first five years.⁴⁸⁷ The study also discovered that over

8,000 oil and gas wells drilled since 2000 had not received a facility-level inspection. This study helps explain the results of earlier studies that documented elevated levels of methane in drinking water aquifers located near drilling and fracking operations in Pennsylvania and points to compromised structural integrity of well casings and cement as a possible mechanism.

- May 22, 2014 – In a 69-page report, University of Waterloo researchers warned that natural gas seeping from 500,000 wellbores in Canada represents “a threat to environment and public safety“ due to groundwater contamination, greenhouse gas emissions, and explosion risks wherever methane collects in unvented buildings and spaces. The report found that 10 percent of all active and suspended gas wells in British Columbia now leak methane. Additionally, the report found that some hydraulically fractured shale gas wells in that province have become “super methane emitters” that spew as much as 2,000 kilograms of methane a year.^{488, 489}
- May 1, 2014 – Following a comprehensive review of evidence, the Council of Canadian Academies identified inherent problems with well integrity as one of its top concerns about unconventional drilling and fracking. According to one expert panel, “the greatest threat to groundwater is gas leakage from wells from which even existing best practices cannot assure long-term prevention.”⁴⁹⁰ Regarding their concerns related to well integrity and cement issues, the panel wrote:

Two issues of particular concern to panel members are water resources, especially groundwater, and GHG emissions. Both related to well integrity.... Natural gas leakage from improperly formed, damaged, or deteriorated cement seals is a long-recognized yet unresolved problem Leaky wells due to improperly placed cement seals, damage from repeated fracturing treatments, or cement deterioration over time, have the potential to create pathways for contamination of groundwater resources and to increase GHG emissions.

They further explain:

Cement may crack, shrink, or become deformed over time, thereby reducing the tightness of the seal around the well and allowing the fluids and gases ... to escape into the annulus between casing and rock and thus to the surface.... The challenge of ensuring a tight cement seal [will] be greater for shale gas wells that are subjected to repeated pulses of high pressure during the hydraulic fracturing process than for conventional gas wells. This pressure stresses the casing and therefore the cement that isolates the well from surrounding formations

repeatedly.

- January 8, 2013 – According to state inspections of all 6,000 wells drilled in Pennsylvania’s Marcellus Shale before 2013, six to ten percent of them leaked natural gas, with the rate of leakage increasing over time. The rate was six percent in 2010 (97 well failures out of 1,609 wells drilled); 7.1 percent in 2011 (140 well failures out of 1,972 wells drilled); and 8.9 percent in 2012 (120 well failures out of 1,346 wells drilled).⁴⁹¹ These data include wells that were cited for leakage violations, and wells that were noted to be leaking by inspectors but which had not been given violations. The NYS DEC forecasts that 50,000 wells could be drilled over the life of the Marcellus Shale play. If they fail at the same rate as wells in Pennsylvania, 4,000 wells would fail and leak in New York almost immediately.⁴⁹²
- March 2009 – A study published by the Society of Petroleum Engineers of more than 315,000 oil, gas, and injection wells in Alberta, Canada, found that 4.5 percent of the wells had unintended gas flow to the surface. In one designated area, officials required testing for gas migration outside the well casings in addition to routine testing for gas leaks within the rings of steel casings (annuli). Within this special testing zone, 15.5 percent of wells (3,205 of 20,725) leaked gas, and the incidence of gas leaks was four times percent higher in horizontal or deviated wells than in vertical wells.⁴⁹³
- Autumn 2003 – Schlumberger, one of the world’s largest companies specializing in hydraulic fracturing and other oilfield services, reported in its in-house publication, *Oilfield Review*, that more than 40 percent of approximately 15,500 wells in the outer continental shelf area in the Gulf of Mexico were leaking gas. These included actively producing wells, in addition to shut-in and temporarily abandoned wells. In many cases, the gas leaked through the spaces (annuli) between layers of steel casing that drilling companies had injected with cement precisely to prevent such gas leaks. Leakage rates increased dramatically with age: about five percent of the wells leaked immediately; 50 percent were leaking after 15 years; and 60 percent were leaking after about 30 years.⁴⁹⁴ Gas leaks pose serious risks including loss of life from explosions and migration of gas and associated contaminants into drinking water supplies. Leaks also allow the venting of raw methane into the atmosphere where it acts as a powerful greenhouse gas.

Waterloo in Ontario, and two co-authors presented a paper published by the Society of Petroleum Engineers, in which they reported that oil and natural gas wells routinely leak gas through cracks in their cement casings, likely caused by cement shrinkage over time and exacerbated by upward pressure from natural gas. According to their paper, in Alberta, it is common for wells to leak natural gas into aquifers. “Because of the nature of the mechanism, the problem is unlikely to attenuate,” they wrote, “and the concentration of the gases in the shallow aquifers will increase with time.”⁴⁹⁵

Radioactive releases

Exemptions from federal hazardous waste laws mean that no national regulatory framework exists for handling the radioactive materials in solid and liquid fracking waste. Instead, regulation is the responsibility of individual states, which vary widely in their approaches. High levels of radiation documented in fracking wastewater from many shale formations raise special concerns in terms of impacts to groundwater and surface water. Measurements of radium in fracking wastewater in New York and Pennsylvania, from the particularly radioactive Marcellus Shale, have been as high as 3,600 times the regulatory limit for drinking water, as established by the U.S. Environmental Protection Agency (EPA). Studies have found toxic levels of radiation in Pennsylvania waterways even after fracking wastewater was disposed of through an industrial wastewater treatment plant.

A study found high levels of radon in buildings located in heavily drilled areas of Pennsylvania, with levels of radon rising since the start of the fracking boom. Unsafe levels of radon and its decay products in natural gas produced from the Marcellus Shale may also contaminate pipelines and compressor stations, as well as pose risks to end-users when allowed to travel into homes. Increasing evidence documents illegal, haphazard dumping of radioactive fracking waste, along with its disposal in municipal landfills not engineered to contain radioactivity. Drill cuttings—the pulverized rock pulled up during the drilling process—are a special concern as this form of solid waste, generated in prodigious amounts, is typically disposed of in municipal landfills lacking special protections for hazardous waste. Radioactivity in drill cuttings has been shown to exceed, in some cases, the regulatory limits for landfills that accept fracking waste. New research suggests that the chemical composition of fracking fluid itself helps to mobilize radioactive materials in the shale.

- March 15, 2019 – Due to a 1980 hazardous waste exemption from the Resource Conservation and Recovery Act (RCRA), drill cuttings from oil and gas fields became exempt from federal oversight, leaving it to states to regulate the disposal of this solid waste stream. A team of researchers measured radioactivity in drill cuttings extracted from Pennsylvania wells and found levels of radium-226 and radium-228 that exceeded the regulatory limits for landfills in Ohio and New York, two states where there are regulatory limits and that accept fracking waste from other states, including from Pennsylvania. The authors recommended rescinding the RCRA exemption for hazardous fracking waste to better protect public health.⁴⁹⁶
- August 3, 2018 – A two-part study by Dartmouth College researchers investigated the source of radium in fracking wastewater from Marcellus Shale wells. By comparing the isotopic ratios, they showed that the high salinity of the wastewater is responsible for extracting radium from the shale. “Experimental results and wastewater data together provide a coherent picture, that the distinctive Ra isotopic signature of Marcellus wastewaters results from contemporaneous water-rock interactions that promote

⁴⁹⁶ Swiedler, E. W., Muehlenbachs, L. A., Chu, Z., Shih, J.-S., & Krupnick, A. (2019). Should solid waste from shale gas development be regulated as hazardous waste? *Energy Policy*, 129, 1020-1033. doi: 10.1016/j.enpol.2019.02.016

desorption of ²²⁶Ra from organics during hydraulic fracturing.”⁴⁹⁷ In the second part of the study, the researchers used mass balance and isotope mixing models to attribute both the extreme salinity and the presence of radium in liquid fracking waste to the progressive, hydrologic enrichment of injected fluids during hydraulic fracturing.⁴⁹⁸ In sum, the chemical composition of fracking fluid itself and its interactions with black shale during the fracking process combine to make fracking waste radioactive. Explaining these findings in a news article, co-author Makul Sharam said, “Radium is sitting on mineral and organic surfaces within the fracking site waiting to be dislodged. When water with the right salinity comes by, it takes it on the radioactivity and transports it.”⁴⁹⁹

- February 19, 2018 – A study conducted in the Bakken Shale region of North Dakota used a multivariate regression model to predict radium-226 levels in fracking wastewater based on levels of other elements (barium, strontium, calcium). Their simulation model gave results that align with the extremely limited actual data based on direct measurements of radionuclides in Bakken Shale wastewater. The research team then used their model to predict potential harm to human health based on spills into surface water that is issued as a source of drinking water, irrigation, and recreational fishing. Even in the best-case scenario, using simulated concentrations on the low end, the results indicated that “there is potential risk to human health” in North Dakota due to radium-226 in fracking wastewater spills. This model can be used for any area where oil and gas waste is produced. “Overall, the results presented in this study can be treated as a warning and a reference to conduct further investigations.”⁵⁰⁰
- February 6, 2018 – A research team from City University of New York School of Public Health and Health Policy surveyed the various state-based regulations and state licensing requirements governing the disposal of radioactive waste from oil and gas waste streams. They found that 17 states had drafted express regulations to reduce exposure to radiation from oil and gas waste. States with active oil and gas drilling that lack such regulations “may leave the public and workers susceptible to adverse health effects from radiation.” Among the authors’ policy recommendations: due to accumulation of radioactivity on equipment, future studies should explore impacts on workers; exposed workers should wear badges to monitor exposures; worker exposures should be limited by shift changes; regulations across states should be harmonized to prevent cross-state dumping of large

amounts of radioactive solid waste and assure protection of the public from the risk of radiation from exposure to oil and gas drilling wastes.⁵⁰¹

- January 4, 2018 – A research team from Duke and Pennsylvania State universities collected stream sediments upstream and downstream from three disposal sites in Pennsylvania that receive oil and gas wastewater, treat it, and release it into surface water. While the practice of treating and dumping liquid waste from fracking operations into Pennsylvania streams largely ended in 2011, these three facilities continue to treat and release waste from conventional drilling operations. The researchers consistently detected elevated radioactivity in stream sediments in the vicinity of the outfall compared to upstream areas. The ratios of radium isotopes to their decay products showed that some of the radium had accumulated in the sediments in recent years—after discharges of fracking waste had been halted. Hence, radioactivity from conventionally drilled wells is the likely source of the high levels of radium in sediments downstream from these three treatment plants. Consequently, policies that prohibit disposal only of fracking waste fluids “are not adequate in preventing radioactive contamination in sediments at disposal sites.” Permission to treat and release any type of oil and gas wastewater via centralized waste treatment facilities “should be reconsidered.”⁵⁰²
- September 22, 2017 – State health regulators confirmed that unknown quantities of radioactive waste from drilling and fracking operations have been illegally buried in Colorado landfills not permitted to accept it.⁵⁰³
- November 23, 2016 – University of Iowa researchers evaluated radioactive materials—uranium, thorium, radium, lead, and polonium isotopes—from drill cutting samples extracted from a single well drilled in northern Pennsylvania. They found complex patterns of vertical stratification. For example, the deep drill cuttings had significantly more uranium (U) than the cuttings removed from shallow portions of the well. Noting that virtually all drill cutting waste from the Marcellus Shale is deposited in landfills, the authors examined the stability of the various radioactive materials by simulating different conditions of landfill leaching. The results suggested some environmental mobility of radionuclides in drill cuttings. In particular, as acidity increased, radionuclide leaching increased, with ²³⁸U and ²³⁴U being the most leachable radionuclides. The authors concluded, “Although previous studies have suggested that [radioactive materials] in drill cuttings pose a minimal health risk to the general public when deposited in landfills, our

results indicate that Marcellus Shale drill cuttings warrant further radiochemical investigation.”⁵⁰⁴

- April 27, 2016 – Duke University researchers who studied oil and gas wastewater (“brine”) spills reported that “the water contamination from brine spills is remarkably persistent in the environment, resulting in elevated levels of salts and trace elements that can be preserved in spill sites for at least months to years” In addition, radioactivity was elevated in soil and sediment sampled at spill sites, indicating that radium had accumulated in the soils of spill-affected areas.⁵⁰⁵ The bigger the spill, the higher the soil radioactivity level. Study author Avner Vengosh told *InsideClimate News*, “We found even if you take away the spill water... you still left behind the legacy of radioactivity in the soils,” where it can linger for thousands of years.⁵⁰⁶
- March 10, 2016 – Louisville’s *Courier-Journal* reported on illegal dumping of radioactive oil and gas drilling wastes in two Kentucky landfills. Landfill operators in Greenup and Estill counties were issued violation notices for failing to “accurately characterize the waste for what it was, allowing what’s considered an illegal release of a hazardous material into the environment.” The illegal dumping at the Greenup County landfill alone consisted of 369 tons of radioactive drilling waste.⁵⁰⁷
- February 26, 2016 – Radioactive oil and gas waste from fracking operations in Ohio, Pennsylvania, and West Virginia was illegally sent to Estill County, Kentucky’s Blue Ridge Landfill. The radioactive level of the material that was buried “was at least 340 times more than the amount that is allowed to be buried at a solid waste landfill,” according to WKYT in Lexington. WKYT reported that Estill County leaders would “fight ‘tooth and toenail’ to get the bottom of how low-level radioactive waste ended up in a county landfill,” and do its own testing at the landfill and nearby schools.⁵⁰⁸
- November 23, 2015 – Absence of federal oversight and, in some cases, a total lack of state regulations for handling radioactive oil and gas waste was the topic of a report in *High Country News*, which detailed the regulatory situation in six Western states: Colorado, Idaho, Montana, North Dakota, South Dakota, and Wyoming. North Dakota alone generates an estimated 70 tons a day of radioactive oil and gas waste. “Because the waste is often too radioactive to be disposed of in landfills, it sometimes gets dumped

illegally.” Proposed new rules in North Dakota would raise the radioactivity limit for the waste.⁵⁰⁹

- July 8, 2015 – Radium-226 is the dominant radioactive material in flowback water from hydraulically fractured wells in the Marcellus Shale. A Pittsburgh team of researchers studied its fate in three wastewater storage pits in southwestern Pennsylvania over a 2.5-year period of time. They found that radium-226 concentrations increased when flowback water was being reused for additional fracking operations. Also, radium-226 tended to accumulate in the bottom sludge. This sludge could be classified as radioactive solid waste because it exceeded the radium-226 limit for landfill disposal. A risk assessment showed that potential radiation dose equivalent levels around the three fracking waste pits were within the regulatory limit for the general public.⁵¹⁰
- April 9, 2015 – A Johns Hopkins Bloomberg School of Public Health study found that levels of radon in Pennsylvania homes—a region with some of the highest indoor radon concentrations in the US—have been rising since 2004, around the time the fracking industry arrived in the state.⁵¹¹ Radon exposure is the second leading cause of lung cancer worldwide, after cigarette smoking.⁵¹² Researchers found that buildings in counties where the most fracking has taken place in the past decade have had significantly higher radon readings compared with those in low-fracking areas, a difference that did not exist before 2004. Use of well water was associated with 21 percent higher indoor radon concentrations than in buildings using public water sources. This study, the first to define and evaluate the predictors of indoor radon concentrations in Pennsylvania, concluded that radon’s presence was related to geology, water sources, weather, and natural gas drilling.⁵¹³
- April 2, 2015 – A team of toxicologists, geochemists, and radiation scientists led by the University of Iowa analyzed the contribution of various naturally occurring radioactive materials (NORM) to the total radioactivity of fracking waste fluids, finding evidence of long-lived, environmentally persistent radioactive decay products.⁵¹⁴ “NORM is emerging as a contaminant of concern in hydraulic fracturing/unconventional drilling

wastes, yet the extent of the hazard is currently unknown.” The study determined that previous testing and study methods likely underestimate radioactivity by focusing only on radium. The researchers developed a new method to accurately predict the concentrations of uranium, thorium, and radium and their alpha-emitting progeny, polonium and lead, in fracking wastewater. They found that, under certain conditions, radioactivity increased over time, due to ingrowth of alpha-emitting radioactive progeny of long-lived parent radionuclides such as radium. The authors warned that these decay products may potentially contaminate recreational, agricultural, and residential areas, and that a more detailed understanding is needed of how radionuclides accumulate in higher organisms. In an accompanying article in *Environmental Health Perspectives*, James Burch, a University of South Carolina epidemiologist who was not involved in the study, said that fracking activities and wastewater disposal, which often take place in close proximity to where people live and work, raise risks for human exposure. “The technology is vastly outpacing what we know about the health effects.”⁵¹⁵

- May 8, 2014 – A group of leading medical experts and the American Lung Association of the Northeast detailed research and growing concerns about potential health impacts of radon and radium associated with natural gas production and the Marcellus Shale, in particular. High levels of radiation in the Marcellus Shale could pose health threats if high concentrations of radon and its decay products travel with natural gas, a problem compounded by the short distance Marcellus gas could travel in pipelines to people’s homes.⁵¹⁶
- March 24, 2014 – A team led by toxicology researchers at the University of Iowa identified high levels of radioactivity in fracking wastewater as a significant concern and noted that the testing methods used and recommended by state regulators in the Marcellus Shale region can dramatically underestimate the amount of radioactivity—specifically radium—in fracking wastewater.⁵¹⁷ Results obtained using EPA-recommended protocols can be obscured by the presence of other contaminant mixtures. Regarding the use of EPA protocols with fracking wastewater or other highly saline solutions, Duke University geochemist Avner Vengosh noted, “People have to know that this EPA method is not updated.”⁵¹⁸
- February 2014 – The Marcellus Shale is known to have high uranium and radium content. According to Mark Engle, USGS geochemist, the concentration of radium-226 can exceed 10,000 picoCuries/Liter (pCi/L) in the shale. Radium-226 has a half-life of

1,600 years. Radium and other naturally occurring radioactive materials (NORM) can be released from shale rock during drilling and fracking and can emerge with flowback and produced waters. It can thus enter the ambient environment and become concentrated in the sludge that results from treatment of flowback water, and in river sediment around water treatment facilities. It can also be found in landfills in which sludge and sediment have been disposed. Some radium can be found in drinking water. Geochemist Avner Vengosh warned, “Once you have a release of fracking fluid into the environment, you end up with a radioactive legacy.”⁵¹⁹

- October 2, 2013 – A peer-reviewed study of the impacts of drilling wastewater treated and discharged into a creek by a wastewater facility in western Pennsylvania documented radium levels approximately 200 times greater in sediment samples near the discharge location than in sediment samples collected upstream of the plant or elsewhere in western Pennsylvania. “The absolute levels that we found are much higher than what you allow in the U.S. for any place to dump radioactive material,” one of the authors told *Bloomberg News*. The pollution occurred despite the fact that the treatment plant removed a substantial amount of the radium from the drilling wastewater before discharging it. The researchers wrote that the accumulation of radium in sludge removed from the wastewater “could pose significant exposure risks if not properly managed.”^{520, 521}
- February 2013 – In an analysis of fracking sludge samples from Pennsylvania, researchers “... confirmed the presence of alpha, beta, and gamma radiation in the soil and water in reserve pits located on agricultural land.” Total beta radiation exceeded regulatory guideline values by more than 800 percent, and elevated levels of some of the radioactive constituents remained in a vacated pit that had been drained and leveled. It is imperative, the research team concluded, “that we obtain better knowledge of the quantity of radioactive material and the specific radioisotopes being brought to the earth’s surface from these mining processes.”⁵²²
- July 26, 2012 – Responding to concern about radon in natural gas produced from the Marcellus Shale, the USGS analyzed ten samples of gas collected near the wellheads of three Pennsylvania gas wells. The agency found radon levels ranging from 1-79 picocuries per liter, with an average of 36 and a median of 32. (The highest radon activity reported here would decay to 19.8 pCi/L in approximately a week; by comparison, the EPA’s threshold for indoor air remediation is 4 pCi/L.) Asserting they knew of no

previous published measurements of radon in natural gas from the Appalachian Basin, which contains the Marcellus Shale, agency scientists concluded that the number of samples “is too small to ... yield statistically valid results” and urged “collection and interpretation of additional data.”⁵²³

- January 11, 2012 – In its review of the New York State Department of Environmental Conservation’s (NYS DEC) Supplemental Generic Environmental Impact Statement (SGEIS) on high volume fracturing, the EPA expressed concerns about the diffusion of responsibility for the ultimate disposal of radioactive wastes generated by treatment or pretreatment of drilling wastewater. The EPA also raised concerns about the lack of analysis of radon and other radiation exposure. “Who is responsible for addressing the potential health and safety issues and associated monitoring related to external radiation and the inhalation of radon and its decay products?” the EPA asked. “Such potential concerns need to be addressed.”⁵²⁴
- September 7, 2011 – The USGS reported that radium levels in wastewater from oil and gas wells in New York and Pennsylvania, including those in the Marcellus Shale, “have a distinctly higher median ... than reported for other formations in the Appalachian Basin, and range to higher values than reported in other basins.” The median level of radium found in Marcellus Shale wastewater in New York, 5,490 pCi/L, is almost 1,100 times the maximum contaminant level for drinking water, which is five pCi/L. In other words, if a million gallons of Marcellus Shale wastewater contaminated with the median level of radium found in New York were to spill into a waterway, 1.1 billion gallons of water would be required to dilute the radium to the maximum legal level.⁵²⁵ (The EPA’s health-based goal for radium in drinking water is zero.) Over time, radium naturally decays into radioactive radon gas. Thus, higher radium levels also suggest that higher levels of radon may also be present in natural gas produced from the Marcellus Shale.
- February 27, 2011 – The *New York Times* reported on the threat to New York’s drinking water from Pennsylvania drilling waste due to the presence of chemical contaminants, including high levels of radioactivity. The investigation found that sewage treatment plants were neither testing for nor capable of removing that radioactivity, which was subsequently discharged into waterways that supply drinking water, and that, in some cases, wastewater contained radium levels that were hundreds of times higher than the drinking water standard. Drillers sent some of this waste to New York State for disposal even though, as the article noted, EPA scientists had warned the state about this very

problem in a December 2009 letter that advised against sewage treatment plants accepting drilling waste with radium levels 12 or more times as high as the drinking water standard.⁵²⁶

- 2008-2009 – The New York State DEC found that wastewater from 11 of 13 vertical wells drilled in New York’s Marcellus Shale in 2008 and 2009 contained radium levels ranging from 400 times to nearly 3,400 times EPA’s safe level limit for radium in drinking water. These figures later informed the 2011 study of radium in drilling wastewater conducted by the USGS.⁵²⁷

Occupational health and safety hazards

Drilling and fracking jobs are among the most dangerous jobs in the nation with a fatality rate that is four to seven times the national average. Irregularities in reporting practices mean that counts of on-the-job fatalities among oil and gas workers are likely underestimates. Contract workers are especially at risk. Occupational hazards include head injuries, traffic accidents, blunt trauma, burns, inhalation of hydrocarbon vapors, toxic chemical exposures, heat exhaustion, dehydration, and sleep deprivation. An investigation of occupational exposures found high levels of benzene in the urine of wellpad workers, especially those in close proximity to flowback fluid coming up from wells following fracturing activities. Exposure to silica dust, which is definitively linked to silicosis and lung cancer, was singled out by the National Institute for Occupational Safety and Health (NIOSH) as a particular threat to workers in fracking operations where silica sand is used. At the same time, research shows that many gas field workers, despite these serious occupational hazards, are uninsured or underinsured and lack access to basic medical care.

In 2018, the first independent investigation of its kind showed that pipeline construction workers die on the job 3.6 times more often than the average U.S. worker. Pipeline worker deaths occur from crushings, fires, and heat exhaustion. The number of miles of U.S. pipelines tripled from 2006 to 2016, and newer pipelines are less safe than older ones. Pipelines built after 2010 suffer higher failure rates than pipelines built at any other time.

- February 19, 2019 – An investigation into the death of oil worker Dennis Mason by *E&E News* shows how inhalation of toxic vapors is systematically overlooked as a possible cause of workplace mortality and “indicates that more than four years after worker safety officials started warning of the lethal dangers of inhaling petroleum gases, the danger is still ignored in some corners of the oil patch.”⁵²⁸ NIOSH has linked at least 13 oil worker deaths to inhalation of petroleum gases, such as butane and propane. However, because medical examiners do not always test for the substances, and attribute the deaths to “natural causes,” there are likely more. In this case, The Occupational Safety and Health Administration (OSHA) investigators immediately suspected that Dennis Mason was killed by toxic vapors and sent information and materials to the responsible Oklahoma state medical examiner, but state officials said they did not receive them. These materials included a paper by an occupational medicine specialist describing how exposure to high concentrations of hydrocarbon gases and vapors in an oxygen-deficient atmosphere can result in sudden cardiac death among oil and gas extraction workers. Instead, the medical examiner tested only for illegal drugs and alcohol before attributing his death to natural causes.
- February 13, 2019 – A series of catastrophic explosions and fires at a gas-processing facility in Pascagoula, Mississippi shut the plant down for six months in June 2016. This facility receives raw gas from drilling operations and separates it into natural gas and hydrocarbon liquids, which are used to make petrochemicals. The U.S. Chemical Safety

⁵²⁸ Soraghan, M. (2019, February 19). Missed connections leave questions in oil worker's death. *E&E News*. Retrieved from <https://www.eenews.net/stories/1060121345>

Board’s final report identified “thermal fatigue” as the probable cause of the series of conditions leading to the explosions. A “major loss of containment” in a heat exchanger resulted in the release of methane, ethane, propane, and several other hydrocarbons, which subsequently ignited. The report’s interactive 3D model showed that the heat exchanger used at the Enterprise Plant, as well as at over 500 other U.S. gas processing facilities, is innately vulnerable to thermal fatigue. The timing of the explosions at the Pascagoula Gas Plant, which occurred shortly before midnight, likely prevented injuries. According to the final report, had the event happened during the day, with many more workers present, the consequences could have been much worse. The report noted that many nearby residents chose to evacuate, and afterwards, a local community organization informed the Board that residents did not know how to respond to the explosions. “They felt uninformed and ill equipped to know if they were in harm’s way.” The final report’s recommendations included the development of a “robust and engaged community alert network.”⁵²⁹

- December 21, 2018 – In the decade between 2008 and 2017, 1,566 U.S. workers died from on-the-job injuries in the oil and gas drilling industry and related fields. These figures were derived from data collected by the U.S. Department of Labor’s Bureau of Labor Statistics as part of a special investigative report that included participation by the *Texas Tribune*. In a slightly longer overlapping period, OSHA cited companies in the oil and gas extraction industry for 10,873 violations and investigated 552 accidents that had resulted in at least one worker death. Upstream drilling and fracking operations are exempt from safety rules that govern all downstream sectors of the oil and gas industry. Among these are rules that require refineries, petrochemical plants, and other high-hazard operations to adopt procedures to prevent fires, explosions, and chemical leaks. The investigation detailed a number of specific oil and gas industry deaths in Texas, highlighting the various preventative and regulatory failures associated with traumatic injury; exposure to toxic gases, including hydrogen sulfide; and blowout risk and fires.⁵³⁰
- October 11, 2018 – In addition to social isolation and the wide-ranging effects of job-related stress, the physical costs to wellpad workers are high, according to a qualitative study on oil workers’ social, emotional, and psychological well-being. The study consisted of in-depth interviews with 14 oil industry workers in Alberta, Canada. Twelve were men and two were women. Thirteen of the fourteen workers were employed by third-party contractors. They included heavy-equipment operators, surveyors, health and safety specialists, environmentalists, biologists, wireline engineers, derrick hands, consultants, and drillers. All were rotational workers. Rotational work involves travel to various oil fields and working extended shift schedules, which typically involves 21 consecutive days of work followed by three days off. Most of the respondents said they experienced physical pain on a somewhat regular basis. These findings corroborate the results of other studies reviewed by the authors. “Rotational oil field workers are

⁵²⁹ U.S. Chemical Safety Board. (2019, February 13). *Loss of containment, fires, and explosions at Enterprise Products Midstream Gas Plant*. Investigation Report No. 2016-02-I-MS. Retrieved from https://www.csb.gov/assets/1/6/final_case_study_-_enterprise.pdf

vulnerable to personal, social, and economic stressors that may result in degraded wellbeing.... As we explored here, ‘good jobs’ in the patch come at a steep psychosocial and physical health cost to the labourers.”⁵³¹

- October 10, 2018 – The most “cohesive explanation yet” for one of the worst oil field accidents in U.S. history, the January 2018 Oklahoma well fire which killed five workers, came from a lawsuit based on dozens of depositions. OSHA had sought penalties but did not offer an explanation, and the U.S. Chemical Safety Board stated plans to issue a report over a year later. (See Emerging Trend 6 in the front matter of this report, regarding the findings of the final report.) The factors explained in the lawsuit included ignoring warnings about using a cheaper and lighter drilling mud, and a broken and locked door out of which the five workers may have been able to escape.⁵³² The operating company blamed contractors.⁵³³ (See also entry below for August 16, 2018.)
- September 12, 2018 – In 2016, oil and gas pipeline construction workers died on the job 3.6 times more often than the average U.S. worker, as determined by the first independent investigation to compile and present fatality rates for those who build oil and gas pipelines in the United States. That same year oil and gas pipeline construction workers had the highest death rate and number of deaths for those employed in these jobs since 2012. “If we add the deaths of workers whose job it is to maintain and monitor the pipelines as they carry the fuels (pipeline transport), 2016 was the deadliest year for oil and gas pipeline workers since 2009.”⁵³⁴ Pipeline worker deaths occurred from crushings, fires, and heat exhaustion. The number of miles of U.S. pipelines carrying oil and other hazardous liquids tripled from 2006 to 2016, and newer pipelines are less safe than old ones. Pipelines built after 2010 suffer failures at a higher rate than pipelines built “at any time in the last century,” with pipelines carrying natural gas over five times more disaster-prone. The author made available her complete methodology and references for the project, with a discussion of her methodology and other data sources, including strengths, weaknesses, and comparability. Her stated intention in building a first-of-its kind oil and gas pipeline fatality report was to be “as straightforward and replicable as possible.”⁵³⁵
- August 20, 2018 – Nearly 1,000 workers have been killed in the ten years since hydraulic fracturing and horizontal drilling technologies rapidly expanded, although the current oil and gas worker fatality rate is down from its earlier high at seven times higher than across

all industries. Persistent fatality risk factors include the practice of manual tank gauging, vehicle crashes, and inexperienced workers.⁵³⁶

- August 16, 2018 – On January 22, 2018, five workers were killed during the drilling of a gas well in Pittsburg County, Oklahoma. While the drill pipe was being lifted, a mixture of mud and gas blew upwards out of the well, and the gas subsequently ignited and exploded. A “factual update” as part of the ongoing investigation by the U.S. Chemical Safety Board found that a piece of safety equipment designed to control the release of fluids from the well was unable to fully close on the day of the accident and that other safety corners had been cut.⁵³⁷
- April 29, 2018 – Improper or inadequate use of personal protective equipment was of highest concern in a survey of industry workers and regulators that was designed to find the frequency of “failure incidents” and near misses at wellhead sites. Workers and regulators also cited spills of flowback water due to equipment failure as a major concern, with regard to the welfare of both workers and the general public, as these spills “occur more frequently than any other scenario examined in this study.”⁵³⁸
- April 26, 2018 – There were 63 deaths in oil and gas extraction in 2016, as reported in the 2018 edition of the AFL-CIO report, *Death on the Job, The Toll of Neglect*. The fatality rate for the overall mining sector, which includes oil and gas extraction, was 10.1 per 100,000 workers, nearly three times the national average. These 63 deaths in oil and gas accounted for 71 percent of the total number of fatal work injuries in the mining sector.⁵³⁹
- March 21, 2018 – The trade publication, *Industrial Safety & Hygiene News*, published a summary of January 2015 to February 2017 oil and gas extraction worker “incidents,” which included 481 hospitalizations and 166 amputations. The article outlined the data gaps and limitations that make accurate tallies of severe injuries in upstream oil and gas operations hard to calculate:
 - State-run OSHA programs are not included in the count.
 - Reporting errors and underreporting are common. Based on workers compensation data, underreporting is estimated at 50 percent; self-reported incidents may lack crucial detail or information.
 - OSHA jurisdiction does not cover incidents that occur on public streets, highways, or during commuting.

- Trucking/hauling related incidents may be listed under other [National Association of Insurance Commissioners] codes.⁵⁴⁰
- December 6, 2017 – Two occupational fatalities and numerous injuries resulted from explosions and fires along oil and gas pipelines in Colorado in the time since two men were killed at home from such a blast in April 2016, according to a *Denver Post* investigation. One contract worker was killed and two others were injured in May while they “were changing ‘dump lines’ and ‘one or more tanks exploded,’ according to a report filed in [Colorado Oil and Gas Conservation Commission’s] database.” Another worker died of his burn injuries from a flash fire in November that broke out during work on a pipeline. “The COGCC did not receive a report on this incident... because the pipeline was a ‘gathering line’ outside the agency’s regulatory purview.” The investigation documented additional gaps in regulatory oversight and responses to deaths and injuries.⁵⁴¹
- October 1, 2017 – An investigation by the *Toronto Star*, the *National Observer*, *Global News*, and four Canadian journalism schools reported on hydrogen sulphide (H₂S)-related health threats and incidents (including one occupational death) in Saskatchewan, and government and industry failure to prevent, warn, and respond to this threat. The more than 50 reporters involved “examined thousands of industry and government documents, analyzed terabytes of data and delved into dozens of freedom-of-information requests,” documenting, for example, the existence of government data describing H₂S “hotspots” across the province, that were never released to the public despite agency deliberations. In addition, reporters wrote,

Ministry and industry met four times between 2012 and 2014 to plot strategy, including emergency planning zones, a public communications document, a code of practice and a licensing regime for high-risk, single-well batteries. Those plans were never adopted, a ministry statement confirms.

An industry salesman was killed in 2014 while taking samples. A valve broke and the concentration of H₂S in the spewed fluids, according to the company, “was estimated at 40,000 parts per million, more than enough to bring near-instant death.” The investigation found that four months after the death, “a secret ministry report listed 161 facilities ‘that may be in violation of (the ministry’s) sour gas emission control.’”⁵⁴²

- August 24, 2017 – NIOSH’s Fatalities in Oil and Gas Extraction (FOG) database identified 88 fatal incidents accounting for 101 fatalities, for the year 2014. In ten of the 88 incidents, more than one worker was fatally injured. The FOG database was established to collect detailed information about deaths related to U.S. oil and gas extraction. The report, which represents only a portion of the deaths that occurred in the industry due to the focus and limitations of the database, aims to provide a deeper understanding of the circumstances of the fatalities, such as the industry group the worker was employed by, and operations and types of activities occurring at the time of the fatal incident. The majority of fatalities in FOG, 45 percent, involved workers employed by servicing companies. These servicing company worker fatalities occurred throughout oil and gas extraction operations: completions (14 fatalities), production (11 fatalities), and well servicing, workover, or intervention (5 fatalities). The industry group responsible for the second highest number of fatalities was drilling companies, at 27 percent, with most of those deaths occurring during drilling operations (20 fatalities). FOG data for 2015-2016 data was not yet available.⁵⁴³
- May 30, 2017 – In a “rare, but not unprecedented” case, the U.S. Environmental Protection Agency (EPA) opened an investigation of air emissions from two North Dakota oil well sites where worker deaths occurred in 2012 and 2014. EPA requested information from both companies to determine Clean Air Act compliance on the day of the deaths. According to the *E&E News* report, it was not clear whether the agency was “looking at civil or criminal sanctions.” Both workers, who were “flow testers,” “assigned to regularly measure tank levels by hand,” were found dead near tank hatches.⁵⁴⁴ (No further information could be located on this investigation.)
- April 28, 2017 – Fatality rates for oil and gas extraction workers associated with falls increased two percent per year during 2003–2013, according to the Centers for Disease Control and Prevention’s *Morbidity and Mortality Weekly Report*. These 63 fatal falls represented 15 percent of the fatal events among this group in the time period. The majority of those who were killed by falls worked for drilling contractors. In the vast majority of cases, “fall protection was required by regulation, but it was not used, was used improperly, or the equipment failed.” Authors noted several limitations of their report, such as the lack of information on self-employed workers and lack of detail in some fatality reports.⁵⁴⁵
- April 26, 2017 – The 2017 edition of the AFL-CIO report, *Death on the Job: The Toll of Neglect*, which reported on the year 2015, showed that, although the number of deaths in the oil and gas extraction industries decreased compared to 2014 (89 compared to 144), employment in oil and gas extraction also decreased from 613,783 in 2014 to 533,184 in

2015. The deaths in the oil and gas extraction industries “accounted for 74% of the fatal work injuries in the mining sector.” Referring to the challenges of getting a firm handle on statistics in this industry, the report stated that, “[f]atality rate data for the oil and gas industry are limited, but available data during the past seven years show fatality rates in oil and gas extraction that are four to seven times the national fatality rate.” Further, “[n]ot surprisingly, states with large amounts of oil and gas activity also have high job fatality rates.” Citing the continuing problem of assigning cause of death in the case of possible inhalation of toxic fumes, the report stated, “[w]hile some deaths are appropriately classified as inhalation deaths, others can be labeled as cardiac arrhythmia or respiratory failure, without further investigation as to whether the health event was induced by acute chemical exposure.” As in previous years, the report expressed concerns about the regulatory gaps in controlling a range of potentially fatal hazards in the industry.⁵⁴⁶

- February 1, 2017 – Caused by exposure to silica particles or dust, silicosis is a progressive, autoimmune disease that scars lung tissue and restricts the ability to breathe. Any level of exposure to respirable crystalline silica can trigger silicosis. A special report on the history of silicosis in the *Journal of Environmental Health* provided background on silicosis as a workplace threat in various industries and identified drilling and fracking operations as a source of contemporary exposure. The report predicts a future cluster of silicosis among well pad workers, noting that research has already identified “unacceptable levels” of silica dust in air samples collected at fracking operations and that workers are seldom offered appropriate respiratory equipment to prevent exposure. Fracking “has the potential for future clusters of silicosis cases to emerge.”⁵⁴⁷
- February 1, 2017 – University of Tennessee Civil and Environmental Engineering faculty investigated the occupational inhalation risks from the emissions of chemical storage tanks in 60,644 fracking wells. They also analyzed the combined occupational inhalation risks caused by open flowback pits and the storage tanks. They used AERMOD, the air pollution dispersion modeling system developed by the American Meteorological Society and EPA, and inhalation risk assessment to determine potential acute non-cancer, chronic non-cancer, acute cancer, and chronic cancer risks. Their results showed the percentage of wells presenting these risks were 12.41, 0.11, 7.53, and 5.80, respectively. They also found that the storage tanks presented the majority of the cancer risks, and the non-cancer risks were associated primarily to the open pits. The known human carcinogen formaldehyde was “the dominant contributor” to both acute (4,267 wells) and chronic (3,470 wells) cancer risk. Authors also reported that volatile organic compound (VOC) emissions from nearby wells and other on-site sources means that the data used in their study “were lower than reported concentrations from field measurements where higher occupational inhalation risks for exposure may be expected.”⁵⁴⁸

- January 19, 2017 – A group of Canadian physicians published a report documenting ten intentional intoxications from the ingestion of fracking fluid. Each individual survived, which the authors attribute to “[r]apid case finding and diligent contact tracing.” Their report, published in the *American Journal of Kidney Diseases*, focused on this appropriate response and treatment, but also described the “outbreak” challenge from a public health perspective and emphasized the need for prevention education and “requiring secure storage of these products.” Though the professions or workplaces of the patients are not described, presumably they were oil and gas industry workers with easy access to fracking fluid.⁵⁴⁹
- September 25, 2016 – A four-chapter investigative series by the *Denver Post* explored in detail Colorado’s 12-year record of an oil and gas worker dying, on average, every three months. The piece documented the obstacles present in even clarifying the occupational mortalities owing to the differing reporting practices of the Bureau of Labor Statistics, OSHA, and state officials. “Regulation is so disjointed that no one can even agree on the number of workers killed on the job.” Investigating the details of the deaths through any available records, the *Post* described a “regulatory vacuum,” as well as “little consequence” to the industry when deaths (or worksite violations) occur. Worker death circumstances examined in the piece included electrocutions, falls and collapsed structures, crushings by equipment, explosions, and a drowning in frack sand. The *Post* also identified five lawsuits over 15 years “in which workers alleged that they were punished for reporting injuries or safety hazards.”⁵⁵⁰
- April 27, 2016 – According to the 2016 edition of the AFL-CIO report, *Death on the Job: The Toll of Neglect*, the fatality rate for workers in the oil and gas extraction industries is nearly five times the national average, and the states with prominent oil and gas industries are among the most dangerous states to work. In addition, the report emphasized, the industry has been exempted from some critical OSHA standards, including that for carcinogenic benzene. The report also emphasized the danger of silica dust exposure in hydraulic fracturing-related work and the significant delays in controlling workers’ exposures in these operations. “Oil and gas extraction is subject to OSHA general industry and construction regulations, none of which are designed to address the particular safety and hazards in the oil and gas industry.... The escalating fatalities and injuries in the oil and gas extraction industry demand intensive and comprehensive intervention,” the report stated.⁵⁵¹
- April 21, 2016 – According to an updated report from the Bureau of Labor Statistics, fatal work injuries in oil and gas extraction industries in 2014 reached a new high of

- February 29, 2016 – *Inside Energy*'s report on high rates of hydrocarbon vapor poisoning among oilfield workers noted that an outdated reliance on manual measurements rather than automated monitoring contributes to ongoing toxic exposures of workers. Under federal oil and gas regulations, oil companies are effectively required to send workers “up on oil and gas tanks to manually measure crude oil, putting them at risk.” The report explained that the Bureau of Land Management (BLM) allows just one kind of automated measurement. The method is expensive and uncommonly used: “there are only 1,500 in use, compared to more than 83,000 oil tanks on federal land. By being so inflexible, BLM’s outdated rules make it very hard to use safer oil measuring devices while making manual oil tank measurement—which endangers workers—the most viable option for companies.”⁵⁵³
- February 19, 2016 – The fatal injuries of a backhoe operator who struck and hit an unmarked, high-pressure gas line in July 2015 prompted an investigation by *StateImpact* in Pennsylvania. The news group noted that “there are no local, state or federal rules on how deep the lines should be buried underground, or even if they’re buried at all. There are no standards for building and maintaining the lines. They don’t have to be marked. And the operator of the line doesn’t have to participate in PA One Call [a statewide communications system for preventing damage to underground facilities], which led to the fatality in Armstrong County.”⁵⁵⁴
- January 15, 2016 – In a publication in Centers for Disease Control’s *Mortality & Morbidity Weekly Report*, researchers urged local and state epidemiologists and medical examiners to not overlook hydrocarbon exposure as an underlying cause of death in gas and oil field workers. “Health and safety professionals need to recognize and act on nonfatal warning signs and symptoms, such as dizziness, confusion, immobility and collapse in oil and gas workers who might have been exposed to high concentrations of [hydrocarbon gas vapors] and to [oxygen]-deficient atmospheres.” Only three of nine deaths that occurred between 2010 and 2015 in the oil and gas fields west of Appalachia were ruled by coroners to have resulted from exposure to gas vapors, although all nine had opened hatches of storage tanks and were exposed to hydrocarbon vapors and oxygen-deficient air.⁵⁵⁵ The *Pittsburgh Post-Gazette* quoted emeritus professor at the University of Pittsburgh Bernard Goldstein saying, “Occupational health experts also

suspect that some deaths involving fires, falls, crashes and mishandling of equipment have resulted from faulty judgement or ‘wooziness’ associated with hydrocarbon vapor exposure ... [b]ut that underlying factor rarely shows up in fatality reports.”⁵⁵⁶

- December 14, 2015 – As reported in the *Guardian*, the suicide rate in the Canadian province of Alberta spiked by 30 percent spike in the first half of 2015, possibly linked to the boom-and-bust cycle of the fracking industry. At the time of reporting, 40,000 jobs had been lost in Alberta since the drop in oil prices in late 2014. Mental health professionals interviewed for the report included Edmonton social worker Leonard McEwan, who specializes in clinical crises intervention and whose patients include those directly or indirectly employed in the oil fields, noticed a sharp increase in suicides after the recent plunge in oil prices. As revealed in the investigative report, three in every four Alberta suicides are male and the vast majority are under 55. Gladys Blackmore, executive director of a mental health program that targets those employed in the industry, believes that young, male workers “living high-risk lifestyles, often in work camps, where they ‘fly-in/fly-out’ for up to 24 days at a time” are particularly vulnerable.⁵⁵⁷
- November 7, 2015 – The *Denver Post* reported on a “new federal database that was developed to more precisely capture the deadly nature of oil and gas extraction.” For Colorado, the national Fatalities in Oil and Gas Extraction (FOG) database contained two additional oil and gas worker deaths for 2014 than did the Bureau of Labor Statistics. “‘We knew from the Bureau of Labor Statistics data about the basics of what’s killing workers,’ said Kyla Retzer, an epidemiologist who led the effort to compile the FOG report. ‘We just wanted to be more in-depth in finding out what were the types of operations and equipment were involved in these deaths.’”⁵⁵⁸ (See entry for August 24, 2017 above for official report.)
- November 4, 2015 – San Antonio’s *Express-News* Editorial Board called for specific actions to address Texas’s status “a national leader in oil field deaths.” The Board wrote that federal fines are too low and unchanged since 1991 and that there is no Level 1 trauma center south of San Antonio near the region’s oil- and gas-producing counties.⁵⁵⁹

- September 17, 2015 – The Bureau of Labor Statistic reported that the number of fatal work injuries in oil and gas extraction industries rose 27 percent between 2013 and 2014.⁵⁶⁰
- September 15, 2015 – E&E Publishing’s *EnergyWire* reported on the potentially deadly risk of exposure to vapors from oil and gas field storage tanks, including deaths that were officially attributed to cardiac arrest, though inhalation of toxic gases and lack of oxygen played a role, as demonstrated in subsequent litigation. The reporter gave detail on the circumstances of several of the deaths, including that of a long-haul trucker who had heart disease and was diabetic, and whose death was classified as natural. “But he didn’t suffer a heart attack that day, or a diabetic episode. Medical experts said he likely wouldn’t have died outside the toxic atmosphere on the catwalk.” A Denver cardiologist testified that “there was no other reason for him to have died that day.”⁵⁶¹ (NIOSH has subsequently targeted outreach to medical examiners to improve their recognition of this hazard and potential cause of death; see above.)
- September 5, 2015 – In partnership with Rocky Mountain PBS I-News, *The Durango Herald* reported on the oil and gas industry’s varied practices in their handling of silica sand with regard to worker protection. In 2012 the National Institute for Occupational Safety and Health issued an alert concerning workers at fracking sites being exposed to silica dust at levels that exceeded occupational exposure limits. Industry has resisted updates to the standards. The *Herald* report addressed technological and work practice controls to reduce exposure on the part of some companies. Still, authors wrote, silicosis “can hide for a decade before causing symptoms. No one knows how many oil and gas workers may have already been exposed.”⁵⁶²
- June 29, 2015 – An investigation by the Center for Public Integrity (CPI) found that lung-damaging silica is not sufficiently regulated to prevent silicosis (which is incurable and has no effective treatment) or lung cancer in the workplace. Rules governing occupational exposure to silica dust are far outdated, and advocacy efforts to tighten them are four decades old. At particular risk, say the authors, are workers in oil and gas fields where silica sand is used in fracking operations. Citing research by NIOSH, the CPI team noted that nearly 80 percent of the air samples on the well pads were above the recommended exposure limit for silica dust.⁵⁶³

- June 15, 2015 – *EnergyWire* examined issues surrounding exposure to crystalline silica from frack sand mining, which is a health concern to those living near mines and to those working in the industry. Families living near industrial sand mining reported that their health has been compromised by sand mine development and are concerned that companies are not properly monitoring their extraction sites. The article noted that OSHA is working on a new exposure rule for workers that the agency estimates would save nearly 700 lives and prevent 1,600 new cases of silicosis annually. The oil and gas industry is fighting the rule because of the cost associated with complying with a more stringent permissible exposure limit. Crispin Pierce, public health researcher at the University of Wisconsin in Eau Claire, is in the midst of a three-pronged research project to look at the industry’s air effects. Among other findings, his project’s air monitors around sand plants have found consistently finding higher readings than the Wisconsin Department of Natural Resources’ reported regional values.⁵⁶⁴
- June 15, 2015 – In an update, NIOSH noted that silicosis death rates are rising again, reversing an earlier, decade-long decline. In the list of job tasks with known high silica exposures, the update named hydraulic fracturing of gas and oil wells. These results are particularly concerning in light of earlier research showing significant under-detection of silicosis among deceased workers with known exposure to silica dust.⁵⁶⁵
- June 13, 2015 – Reporting on North Dakota’s fracking boom, the Center for Investigative Reporting found that the major oil companies have largely written the rules governing their own accountability for accidents. Deeply entrenched corporate practices and weak federal oversight, according to the report, have led to high injury and death rates and a shift of assigned responsibility to others. Using data from U.S. and Canadian regulators, the journalists verified 74 on-the-job deaths among workers in Bakken Shale drilling and fracking operations since 2006. The actual number of deaths is likely higher than currently reported because federal regulators do not have a systematic way to record oil- and gas-related deaths, and OSHA does not include certain fatalities, including those of independent contractors. The report concluded that there was too little oversight from OSHA, that laws to protect workers were outdated, and that there was a culture of self-regulation by the industry.⁵⁶⁶
- May 29, 2015 – The Centers for Disease Control and Prevention published statistics on work-related fatalities during the fracking boom. The occupational fatality rate among U.S. oil and gas industry extraction workers between 2003 and 2013 remained an average of seven times higher than among U.S. workers in general (25.1 versus 3.7 deaths per 100,000 workers per year). Within this 11-year period, the industry doubled the size of its workforce and increased drilling rigs by 71 percent. The number of occupational deaths

increased 27.6 percent, with a total of 1,189 deaths, but it did not increase as much as the number of workers, resulting in an overall decrease in the fatality rate of 36.3 percent. Transportation accidents and contact with objects and equipment were the most frequent fatal events. Evidence suggests that the increased use of automated technologies on drilling rigs may be contributing to the decline in death rates.⁵⁶⁷

- April 22, 2015 – The AFL-CIO published data for job injuries, illnesses and deaths in a national and state-by-state profile of worker safety and health in the United States, presenting comparisons by state and industry. For the third year in a row, North Dakota had the highest on-the-job fatality rate in the nation: 14.9 deaths per 100,000 workers, a rate that is more than four times the national average, and which has more than doubled since 2007. The fatality rate in the mining and oil and gas extraction sector in North Dakota was 84.7 per 100,000, which is nearly seven times the national fatality rate of 12.4 per 100,000 in this industry.^{568, 569}
- April 10, 2015 – In a study that was inclusive of fracking-based extraction but not specific to it, NIOSH researchers updated their investigation into the sudden deaths of nine oil and gas extraction workers found near hatches where hydrocarbons were stored. All nine victims died between 2010 and 2014 and were unobserved or working alone at the time of their deaths. The first report attributed the fatalities to “inhalation of volatile petroleum hydrocarbons.”⁵⁷⁰ The update noted that when workers open hatches on production tanks, a plume of hydrocarbon gases and vapors can be rapidly released due to high internal pressure. Exposure to high concentrations of these low-molecular-weight hydrocarbons creates asphyxiation and explosive hazards and can have narcotic effects, resulting in disorientation, dizziness, and light-headedness. The authors cited reports of other sudden deaths following butane and propane inhalation, exposure to which can induce irregular heartbeat, insufficient oxygen supply, and respiratory depression.⁵⁷¹ As reported by the *Denver Post*, most of the death certificates listed natural causes or heart failure as the cause likely because medical examiners can easily miss signs of toxic inhalation during a routine autopsy. The nomadic nature of the industry presents obstacles to proper training in tank handling techniques.⁵⁷² NIOSH issued

recommendations for worker protections, including respiratory protection training and engineering controls for remote gauging and venting.⁵⁷³

- February 15, 2015 – Burn injuries among North Dakota workers surged to more than 3,100 over the past five years as the area has become the epicenter of a massive drilling and fracking boom, as reported by the *Star Tribune*. Despite the flammability of Bakken crude oil and the danger of oil rig work, North Dakota has no burn centers, and burn victims must be transported out of state, typically to the Minneapolis-St. Paul area some 600 miles away. The article also covered the severe, debilitating, costly, and sometimes fatal aspects of these occupational injuries.⁵⁷⁴
- February 13, 2015 – NIOSH reported that while silicosis death rates declined between 2001 and 2010, silicosis deaths were still occurring among young persons aged 15 to 44 years old, indicating extremely high exposures to respirable silica dust. Among emerging new settings that put workers at risk for silicosis, the authors named oil and gas extraction industry workers.⁵⁷⁵
- January 14, 2015 – The *Charleston Gazette-Mail* reported that, due to an increase in workplace deaths that has accompanied the boom in natural gas drilling and production from the Marcellus Shale fields in Northern West Virginia, the Governor there has called for a study aimed at reversing that trend. “Between 2009 and 2013, as the industry boomed in the Marcellus region, 15 natural gas workers died on the job in West Virginia, according to the federal data. During the previous five-year period, from 2004 to 2008, three workers died in West Virginia’s oil and gas industry, according to the [U.S. Bureau of Labor Statistics].”⁵⁷⁶
- January 12, 2015 – Oil and gas production employs less than one percent of the U.S. workforce, but in the past five years it has had more than ten percent of all workplace fatalities from fires and explosions. A review by *EnergyWire* of federal labor statistics last year found the industry had more deaths from fires and explosions than any other private industry. The only “industry” with more fire and explosion fatalities than oil and gas was firefighting, the report stated. These statistics are inclusive of deaths related to fracking operations but are not specific to them.⁵⁷⁷

- December 26, 2014 – A report in the *Houston Chronicle* illustrated the difficulties oil and gas workers encounter when injured on the job. In one case a worker fell from a rig, injuring his head. Supervisors did not record the accident. After he became too ill to work, he was shifted to other jobs and soon after, sent home. His daughter filed a Worker’s Compensation claim, which was denied for “late reporting, no knowledge of injury by employer and no medical reports.” The article noted that oilfield injuries are generally undercounted nationally. These include injuries related to drilling and fracking operations as well as those linked to other techniques of extraction.⁵⁷⁸
- December 4, 2014 – Benzene, a naturally occurring component of crude oil and natural gas, is a known carcinogen, with no known threshold of safety. Although the American Petroleum Institute in 1948 stated that “the only absolutely safe concentration ... is zero,” the organization since then undertook an intensive campaign to combat strict exposure limits. An investigation by the Center for Public Integrity found that, “[f]or decades, the petrochemical industry spent millions on science seeking to minimize the dangers of benzene.... Taken together, the documents—put in context by interviews with dozens of lawyers, scientists, academics, regulators and industry representatives—depict a ‘research strategy’ built on dubious motives, close corporate oversight and painstaking public relations.”⁵⁷⁹
- December, 2014 – In a report intended to inform employers and workers about the known hazards that result from hydraulic fracturing and flowback operations, OSHA noted that there is no publicly available worker injury, illness, or fatality data specific for fracking or flowback operations. At the same time, more workers are exposed to fracking- and flowback-related hazards due to the huge increase in the numbers of these operations over the past ten years. “In light of this, OSHA has determined that additional information concerning hydraulic fracturing and flowback operations hazards should be provided to educate and protect workers.”⁵⁸⁰
- November 11, 2014 – University of Wisconsin toxicologist Crispin Pierce documented super-fine dust drifting from facilities that process silica sand for fracking operations. Pierce and his team detected silica dust in ambient air near frac sand operations at levels that exceed EPA air quality standards by a factor of four. Occupational exposure to respirable crystalline silica is linked in adult workers to silicosis, lung cancer, and pulmonary tuberculosis. Health threats to the general public from frac sand-related air pollution have not yet been studied directly. One of the first investigations of silica dust levels in the community environment, the Wisconsin study will appear next year in the

- November 11, 2014 – A high-pressure water line ruptured, killing one worker and seriously injuring two others during the hydraulic fracturing of an oil well in Weld County, Colorado.⁵⁸²
- October 6, 2014 – Toxicologist Peter Thorne, chair of University of Iowa’s Department of Occupational and Environmental Health, warned the Winneshiek County Board of Supervisors about potential community impacts and cancer risks of silica exposure from sand used for fracking operations. Thorne’s ongoing investigation, which involves air sampling, risk assessments, and inhalation toxicology studies, focuses on the public health hazards of mining, processing, and storing sand. His team has documented spikes in silica particulate matter related to the transport of the silica sand by rail. The study aims to determine if mining poses an “unacceptable exposure” to the public and quantify the level of risk. For silica-exposed workers, NIOSH continues to identify needed health protections. Thorne noted, “Workers handling materials should be using respirators, but most are not.”⁵⁸³
- September 25, 2014 – The Civil Society Institute's Boston Action Research, in cooperation with Environmental Working Group and Midwest Environmental Advocates, issued a report on the hazards of silica mining. The report noted that frac sand mining is expanding rapidly in the United States and poses a little-understood threat to public health, the environment, and local economies. Given the pace of the drilling and fracking boom, silica extraction could spread to a dozen other states with untapped or largely untapped sand deposits, including Illinois, Maine, Massachusetts, Michigan, Missouri, New York, North Carolina, South Carolina, Pennsylvania, Tennessee, Vermont, and Virginia. The *International Business Times* published a summary of the findings.^{584, 585}
- August 29, 2014 – In a peer-reviewed study, NIOSH partnered with oil and gas operators and service companies to evaluate worker exposures to, and internal uptake of, volatile organic chemicals at six sites in Colorado and Wyoming where wells were being

prepared for production. The study found benzene in the urine of well pad workers. Benzene is “naturally present in flowback fluids and the time spent working around flowback and production tanks ... appears to be the primary risk factor for inhalation exposures.” In some cases, airborne concentrations of benzene exceeded the NIOSH Recommended Exposure Limit concentrations and, in a few instances, the American Conference of Governmental Industrial Hygienists’ Threshold Limit Value, “when workers performed work tasks near a point source for benzene emissions.”⁵⁸⁶

- July 29, 2014 – As part of an investigation into the health impacts of drilling and fracking on animal health, veterinarian Michelle Bamberger and Cornell biochemist Robert Oswald, published an interview with a twenty-year oil and gas industry worker about his experiences and worker safety. His account included injuries, 16-hour workdays, fatigue, exposure to chemicals, and inadequate health and safety training. “No one out there tells you about stuff that has latency. That is the last thing they are going to do is tell you that something that you are handling will take you out in 20 years or 10 years or cause you some kind of ailment, or you can potentially drag this home to your family.”⁵⁸⁷
- July 14, 2014 – As part of an analysis of safety and research needs associated with drilling and fracking, researchers at the Colorado School of Public Health and the College of Health Sciences at the University of Wyoming documented high injury and on-the-job mortality rates among gas and oilfield workers. The occupational fatality rate was 2.5 times higher than that of the construction industry and seven times higher than that of general industry. By contrast, injury rates were lower than the construction industry, suggesting that injuries are underreported. Researchers documented crystalline silica levels above occupational health standards and identified the existence of other hazards, including particulate matter, benzene, noise, and radiation. The team called for exposure assessments for both chemical hazards and physical hazards that lead to occupational illness (noise, radioactivity); screening and surveillance systems to assess incidence and prevalence of occupational illness; industry/academic collaboration to conduct occupational epidemiologic studies; and assessment of the effectiveness of industry interventions to reduce exposures.⁵⁸⁸
- July 2014 – The British labor journal *Hazards* identified health concerns in the drilling and fracking industry: increased rate of death on the job, toxic releases, silica exposure, and exposure to hydrocarbons and endocrine disruptors. The union that organizes the construction, rig, and transport workers, on which fracking would rely, agreed at its July 2014 national conference to lobby for a moratorium on fracking because “[d]elegates want union members to be made aware of the dangers of fracking and be advised not to

work on fracking sites.”⁵⁸⁹

- June 29, 2014, and August 31, 2014 – An initial report and follow-up analysis in *The Columbus Dispatch* examined fire hazards at well pads. In one notable case, malfunctioning hydraulic tubing allowed a well pad fire in Monroe County, Ohio to spread rapidly, prompting evacuations. Local firefighters had neither the correct equipment nor did they know the chemicals they were trying to extinguish. One firefighter was treated for smoke inhalation.^{590, 591}
- May 19, 2014 – Underscoring the dangerous nature of chemicals used in fracking operations, NIOSH reported that at least four gasfield workers have died since 2010 from acute chemical exposures during flowback operations and warned that flowback operations can “result in elevated concentrations of volatile hydrocarbons in the work environment that could be acute exposure hazards.” The agency further noted that such volatile hydrocarbons “can affect the eyes, breathing, and the nervous system and at high concentrations may also affect the heart causing abnormal rhythms.”^{592, 593}
- May 16, 2013 – A NIOSH study revealed that worker exposure to crystalline silica dust from sand used in fracking operations exceeded “relevant occupational health criteria” at all eleven tested sites, and the magnitude of some exposures exceeded NIOSH limits by a factor of 10 or more. “[P]ersonal respiratory protection alone is not sufficient to adequately protect against workplace exposures.” Inhalation of crystalline silica can cause incurable silicosis, lung cancer, chronic obstructive pulmonary disease, kidney disease and autoimmune diseases.⁵⁹⁴ Although community exposures distant from mines are possible, there are no federal or state standards for silica in ambient air.⁵⁹⁵
- May 8, 2014 – A report by the AFL-CIO found that the fracking boom has made North Dakota the most dangerous state for U.S. workers—with a fatality rate five times higher than the national average—and that North Dakota’s fatality rate has doubled since 2007. The AFL-CIO called North Dakota “an exceptionally dangerous and deadly place to

work.” U.S. Secretary of Labor Thomas E. Perez called the rising rate of workplace deaths suffered in the oil and gas sector “unacceptable.”⁵⁹⁶

- April 24, 2014 – A University of Texas San Antonio report commissioned by the Methodist Healthcare Ministries found that many oil and gas field workers in the Eagle Ford Shale are uninsured or underinsured and that “the most noticeable health impacts so far are work-related illnesses and injuries: heat exhaustion, dehydration, sleep deprivation, exposure to oil and gas spills and accidents.” The study also noted that oil and gas production has put strain on healthcare facilities.⁵⁹⁷
- April 10, 2014 – West Virginia University researcher Michael McCawley reported that some of the nation’s highest rates of silicosis are in heavily drilled areas within the Northern Panhandle of West Virginia and southwestern Pennsylvania. A disease that hardens the lungs through inflammation and development of scar tissue, silicosis is entirely attributable to exposure to silica dust, a known occupational hazard at drilling and fracking operations. Two years earlier, OSHA and NIOSH issued a joint “Hazard Alert” to warn fracking workers of the health hazards of exposure to silica dust, including silicosis.⁵⁹⁸
- February 25, 2014 – A year-long investigation by the *Houston Chronicle* found that fracking jobs are deadly, with high fatality rates and high rates of serious injury. Within just one year in Texas, 65 oil and gas workers died, 79 lost limbs, 82 were crushed, 92 suffered burns and 675 broke bones. From 2007 to 2012, at least 664 U.S. workers were killed in oil and gas fields.^{599, 600}
- December 27, 2013 – National Public Radio (NPR) reported spiking rates of fatalities related to oil and gas drilling operations, which had increased more than 100 percent since 2009. NPR noted that in the previous year, 138 workers were killed on the job, making the fatality rate among oil and gas workers nearly eight times higher than the average rate of 3.2 deaths for every 100,000 workers across all industries.⁶⁰¹

- October 30, 2012 – In a policy statement, the American Public Health Association (APHA) asserted that, high volume horizontal hydraulic fracturing (HVHF) “poses potential risks to public health and the environment, including groundwater and surface water contamination, climate change, air pollution, and worker health.” The statement also noted that the public health perspective has been inadequately represented in policy processes related to HVHF.⁶⁰² The policy statement added:

[H]ydraulic fracturing workers are potentially exposed to inhalation health hazards from dust containing silica. There may also be impacts on workers and communities affected by the vastly increased production and transport of sand for HVHF. Inhalation of fine dusts of respirable crystalline silica can cause silicosis. Crystalline silica has also been determined to be an occupational lung carcinogen.

- 2005 – A researcher at Stanford University examined hazards associated with oil and gas extraction from exposure to radiation and determined that inhalation of high levels of radon gas is a serious concern to workers and those living nearby. Because the boiling point of radon lies between those of propane and ethane, gaseous radon (²²²Rn) will concentrate in ethane and propane fractions. “Elevated Rn activity concentration values have been measured at several processing plant sites.... It is well known that the radiological impact of the oil and gas-extracting and processing industry is not negligible.”⁶⁰³
- May 9, 2003 – A New York Medical College study re-evaluated the chest X-rays of patients with exposure to silica who died from various respiratory problems and found that more than eight percent had undiagnosed silicosis. The study suggested that occupational lung disease may be undercounted in high-risk occupations. The authors of this study said that improved OSHA standards, with ongoing exposure monitoring and medical surveillance, would significantly improve the recognition of cases and justify more stringent preventive measures to reduce exposure. They further noted that practitioners need skills in taking an occupational exposure history. Although ten years have passed since this study was published, both recommendations have yet to be implemented.⁶⁰⁴

Public health effects, measured directly

By several measures, evidence for fracking-related health problems has emerged across the United States and Canada. Studies of birth outcomes in regions of intensive unconventional oil and gas extraction continue to point to reproductive risks, including low birth weight and preterm births. In Oklahoma and Colorado, birth defects were elevated among infants whose mothers lived near drilling and fracking sites while pregnant.

As shown by multiple studies in Pennsylvania, as the number of gas wells increase in a community, so do rates of hospitalization, and community members experience sleep disturbance, headache, throat irritation, stress/anxiety, cough, shortness of breath, sinus problems, fatigue, wheezing, and nausea. Also in Pennsylvania, hospitalizations for pneumonia among the elderly are elevated in areas of fracking activity, and one study found significantly elevated rates of bladder and thyroid cancers. In Colorado, children and young adults with leukemia were 4.3 times more likely to live in an area dense with oil and gas wells. Drilling and fracking operations in multiple states are variously correlated with increased rates of asthma; increased hospitalizations for pneumonia and kidney, bladder, and skin problems; high blood pressure and signs of cardiovascular disease; elevated motor vehicle fatalities; symptoms of depression; ambulance runs and emergency room visits; and incidence of sexually transmitted diseases.

Benzene levels in ambient air surrounding drilling and fracking operations are sufficient to elevate risks for future cancers in both workers and nearby residents, according to studies. Animal studies show numerous threats to fertility and reproductive success from exposure to various concentrations of oil and gas chemicals at levels representative of those found in drinking water. A recent study found that 43 chemicals used in drilling and fracking operations are classified as known or presumed human reproductive toxicants, while 31 others are suspected human reproductive toxicants. An earlier study identified two dozen chemicals commonly used in fracking operations as endocrine disruptors that can variously disrupt organ systems, lower sperm counts, and cause reproductive harm at realistically expected exposure levels.

- January 21, 2019 – Increased hospitalizations for diseases of the genitourinary system, such as urinary tract infections, kidney infections, and kidney stones, were “strongly and positively associated with cumulative [unconventional natural gas] well density” in Pennsylvania.⁶⁰⁵ The strongest association for the genitourinary hospitalization rates was for women aged 20 to 64, particularly for kidney infections, stones in the ureter, and urinary tract infections. The researchers compared yearly hospitalization rates for each of Pennsylvania’s 67 counties with the number of new fracking wells drilled, the total number of wells, and the density of wells by land area for each county by year, from 2003-2014. Noting that hospitalizations, in contrast with outpatient physician visits, reflect acute illness or serious exacerbations of chronic disease, the research team pointed

⁶⁰⁵ Denham, A., Willis, M., Zavez, A., & Hill, E. (2019). Unconventional natural gas development and hospitalizations: evidence from Pennsylvania, United States, 2003-2014. *Public Health*, 168, 17-25. doi: 10.1016/j.puhe.2018.11.020

out that these same health problems addressed in an outpatient setting, or not addressed at all, were likely also rising but would not have been counted in this study. The findings also revealed a link between cumulative gas well exposure measures and hospitalization rates for skin problems, particularly among men aged 20 to 64.

- December 12, 2018 – University of Oklahoma public health scientists found a significantly increased prevalence of neural tube defects among children whose birth residence was located within two miles of a drilling and fracking site, compared to those which were not.⁶⁰⁶ The researchers examined records of all 476,600 singleton births and congenital anomalies in Oklahoma from 1997 through 2009, together with historical location and production data on active natural gas wells for each year of the study. No stillbirths were included in this study. Hence, as the researchers note, the link they found would likely be an underestimate “if natural gas activity is related to severe anomalies with high prenatal mortality.”
- December 6, 2018 – Early signs of cardiovascular disease—including high blood pressure, changes in the stiffness of blood vessels, and markers of inflammation—occurred more often in people who live in communities with more intense oil and gas development, according to a study of 97 adults living in northeastern Colorado between October 2015 and May 2016.⁶⁰⁷ Artery stiffness, as measured by augmentation index, was highest among people living in areas with the greatest drilling and fracking activity, as was systolic and diastolic blood pressure (for those not taking prescription medications). This was the first study to evaluate, with direct measurements, indicators of cardiovascular disease and the intensity of oil and gas activity. The results are consistent with previous research showing increased rates of cardiology inpatient hospital admission in these areas.
- August 28, 2018 – The top 10 oil and gas producing counties in Colorado had higher truck accident rates than the remaining 54 counties in an analysis by Colorado School of Public Health researchers. Researchers also performed an additional geospatial study technique called a “grid level analysis” using the Colorado Oil and Gas information System (COGIS), census population information, and home locations. These results showed that grid cells with more homes and/or wells were associated with more truck accidents, as well as with more multi-vehicle truck accidents with an injury.⁶⁰⁸
- August 13, 2018 – Babies in Pennsylvania whose mothers lived near at least one gas well during their pregnancies were at higher risk for adverse birth outcomes, according to a study published in the *Journal of Health Economics*. This investigation examined state-

⁶⁰⁶ Janitz, A. E., Dao, H. D., Campbell, J. E., Stoner, J. A., & Peck, J. D. (2019). The association between natural gas well activity and specific congenital anomalies in Oklahoma, 1997–2009. *Environment International*, 122, 381–388. Advance online publication. doi: 10.1016/j.envint.2018.12.011

⁶⁰⁸ Blair, B. D., Hughes, J., Allshouse, W. B., McKenzie, L., & Adgate, J. L. (2018). Truck and multivehicle truck accidents with injuries near Colorado oil and gas operations. *International Journal of Environmental Research and Public Health*, 15, 1861. doi: 10.3390/ijerph15091861

based data on the locations of 2,459 natural gas wells drilled between 2006 and 2010 together with restricted-access birth and mortality data for the years 2003–2010.⁶⁰⁹ Mothers living within 2.5 kilometers (1.5 miles) of gas wells gave birth to infants with increased incidence of low birth weight and small for gestational age (SGA). SGA generally increases with exposure to environmental pollution and helps determine immediate health care needs, as well as predicting long-term adverse health outcomes. In addition, the study found term birth weight for these infants was lower on average, and the prevalence of APGAR scores less than eight was increased by 26 percent. APGAR scores are used to evaluate the health of infants immediately after birth. This study builds on growing evidence that air pollution from shale gas development damages infant health and stands out for thoroughly controlling for predictors of infant health and for estimating the extensive and intensive margins of drillings. Within the intensive margin (which includes an estimation of the impact of well density), one additional well was associated with a seven percent increase in low birth weight, a five gram reduction in term birth weight, and a three percent increase in premature birth. Each of these adverse outcomes carries high associated medical costs. The author conservatively estimated the added cost associated with one low birth weight infant to be \$96,500 in the first year alone, not counting any loss of parent income. The author noted that these impacts are “likely to persist throughout these children’s lives.”

- August 10, 2018 – A study of Pennsylvania counties focusing on the period 2003–2012 found that counties with fracking activities have higher rates of gonorrhea and chlamydia infections (up 7.8 percent and 2.6 percent, respectively), as well as a 19.7 percent higher rate of prostitution-related arrests.⁶¹⁰ Authors found no evidence that confounding factors such as opioid prescription rates, viral hepatitis deaths, or drug abuse arrests influenced these results. These findings provide “strong evidence that unconventional or shale gas development poses significant risks to public health and that unconventional or shale gas development has policy implications beyond the economic and environmental impacts often cited.”
- July 28, 2018 – Road fatalities in the Permian Basin region of west Texas have risen and fallen with the price of oil, according to an investigative piece in *Bloomberg* using New York Mercantile Exchange and Texas Department of Transportation data.⁶¹¹ Interviewees in the article pointed to inexperienced and exhausted drivers, sinkholes, oversized trucks on roads not designed for the amount of traffic they now carry, and other factors as reasons for the ongoing fatalities.
- July 27, 2018 – In this study of almost 5,000 Pennsylvanians, a team of medical and public health scientists found a link between living closer to more and bigger

⁶¹⁰ Beleche, T., & Cintina, I. (2018). Fracking and risky behaviors: Evidence from Pennsylvania. *Economics and Human Biology*, 31, 69-82. doi: 10.1016/j.ehb.2018.08.001

⁶¹¹ Collins, R., & Adams-Heard, R. (2018, July 28). ‘Death Highway’ is where oil prices, truck fatalities intersect. *Bloomberg*. Retrieved from <https://www.bloomberg.com/news/articles/2018-07-28/-death-highway-is-where-oil-prices-truck-fatalities-intersect>

unconventional shale gas wells and increased symptoms of depression. This is the first epidemiologic study to address a mental health outcome with regard to proximity to fracking and related operations. The researchers combined information from a mailed questionnaire, electronic health record data, and residential proximity to more and bigger wells, using well data from three agencies. Size of wells was ascertained by combining data on total well depth and volume of natural gas produced. Researchers concluded that drilling and fracking activities “may be associated with adverse mental health in Pennsylvania” and called for including potential mental health consequences in future risk-benefit calculations.⁶¹²

- June 21, 2018 – Using individual inpatient data for the whole state of Pennsylvania from 2003 through 2014, researchers found consistent associations between childhood asthma hospitalizations and nearby drilling and fracking activity. When they compared unexposed children to children in the top third of patients exposed to shale gas drilling, the research team found that, during the same calendar quarter a gas well was drilled, the odds of children and adolescents being hospitalized for asthma increased by 25 percent. If there was ever a well drilled within a zip code, the odds of these pediatric asthma-related hospitalizations increased by 19 percent. This finding demonstrates that the increased risk remains for years after wells are drilled.⁶¹³ This study is notable because it is the first to control for 180 pre-existing respiratory health risks. Researchers also considered specific air emissions from drilling and fracking sites. They found that increased levels of 2,2,4-trimethylpentane, carbon dioxide, formaldehyde, nitrous oxide, volatile organic compounds (VOCs), and x-hexane were associated with increased risks of pediatric asthma hospitalizations across age groups, as well as links for younger children to additional pollutants.
- May 21, 2018 – Using the most stringent classification within and across countries internationally, researchers examined reproductive toxicity among chemicals used in drilling and fracking operations for oil and gas. They found that 43 chemicals are classified as known or presumed human reproductive toxicants, while 31 others are suspected human reproductive toxicants. The team, which included Yale School of Medicine and School Public of Health researchers, further analyzed the 43 reproductive toxicants for their carcinogenic and mutagenic properties and found that seven reproductive toxicants doubled as carcinogens and mutagens. They are potassium dichromate, cadmium, benzene, ethylene oxide, nickel sulfate, N,N-dimethylformamide, and lead. Of these, benzene and lead are found in both fracking fluid and in fracking wastewater. Researchers noted that their study was limited to 157 chemicals previously identified as having evidence of reproductive toxicity, which is only a fraction of the more than 1000 chemicals identified as being present in fracking fluid, fracking wastewater, and fracking-related air emissions. They recommended that their framework

⁶¹² Casey, J. A., Wilcox, H. C., Hirsch, A. G., Pollak, J., & Schwartz, B.S. (2018). Associations of unconventional natural gas development with depression symptoms and disordered sleep in Pennsylvania. *Scientific Reports*, 8. doi: 10.1038/s41598-018-29747-2

be extended to all those chemicals.⁶¹⁴ (See also entry for January 6, 2016 in Water Contamination.)

- May 1, 2018 – In a laboratory study, prenatal exposure to fracking-related chemicals triggered immune problems in mice, especially females. All three immune system illnesses tested—a house dust mite-induced allergic disease, influenza A virus, and a disease similar to multiple sclerosis—were impaired in mice exposed in the womb to a mixture of fracking chemicals.⁶¹⁵ Using a chemical mixture “laced with chemicals at levels similar to those found in groundwater near fracking sites” and already demonstrated to have harmful developmental and reproductive effects, the researchers found sex-linked effects.⁶¹⁶ The exposed female mice showed more severe damage to their immune systems and ability to resist disease. In addition, the multiple sclerosis-like disease, experimental autoimmune encephalomyelitis, developed earlier and more severely in female mice as compared to male mice. Authors concluded, “These observations suggest that developmental exposure to complex mixtures of water contaminants, such as those derived from [drilling and fracking] operations, could contribute to immune dysregulation and disease later in life.”
- March 23, 2018 – Yale University public health scientists investigated possible connections between shale gas drilling and sexually transmitted diseases in Ohio. They found that, compared to counties with no shale gas activity, counties with high activity had 21 percent increased rates of chlamydia and 19 percent increased rates of gonorrhea.⁶¹⁷ They classified all 88 counties in the state as having none, low, and high shale gas activity in each year from 2000 through 2016, using Ohio Department of Natural Resources data. Their findings showed magnitude of effect for the association with gonorrhea that is similar to a prior analysis, adding strength to observed associations. Speaking to the *Columbus Dispatch*, the lead author noted, “Although there has been a decrease in new permits in recent years, [sexually transmitted infection] rates continue to climb because once a disease is introduced... it can be exchanged within the communities even after the workers leave.”⁶¹⁸

- March 20, 2018 – In the Texas Barnett Shale, women with homes within a half-mile radius of the most dense gas drilling activity or gas production activity at the time of their child’s birth had, respectively, 20 percent and 15 percent higher risk of preterm birth, compared with women with no such activity near their residence. The greatest proximity-related risk was for extremely premature births (prior 28 weeks gestation): mothers living near the densest drilling activity and the densest production activity were, respectively, 100 percent and 53 percent more likely to give birth to extremely premature babies.^{619, 620} For purposes of this study, the drilling phase included drilling of the wellbore, installation of casing, and fracking, whereas the production phase, which can last for years, included the flowback of gas, condensate, and produced water, as well as possible on-site storage of these materials. Researchers noted that they did not have access to information that would have allowed more refined classification of phases. The study included 13,332 preterm birth cases and 66,933 term births in the 24-county Barnett Shale region between 2010 and 2012. The study also addressed trimester-specific differences in risk, finding little evidence for that factor. (See also entry for September 19, 2017.)
- March 13, 2018 – A research team found higher rates of hospitalizations for pneumonia among individuals ages 65 and older in Pennsylvania counties with drilling and fracking operations compared to those without. This result is consistent with other studies reporting links between respiratory problems and air pollution. This study, which used enhanced county-specific data from 2001 to 2013, expands on earlier research in its geographical reach and longer time horizon. The research team also found higher average hospitalization rates for other air pollution-sensitive diseases (acute myocardial infarction, chronic obstructive pulmonary disease, asthma, and upper respiratory infections) in counties containing unconventional natural gas wells than in those without wells, but those links were not as strong statistically as for pneumonia among the elderly. Noting that their study design may actually underestimate the impact of natural gas development on pneumonia, the research team stated that their study “helps establish a consistent link between unconventional natural gas extraction and higher rates of disease.”⁶²¹
- February 7, 2018 – Female mice exposed to a mixture of 23 fracking chemicals during early life developed dose-specific abnormalities in their mammary glands. The researchers saw changes in tissue morphology, cell proliferation, “and the induction of unique intraductal hyperplasias.”⁶²² (Intraductal hyperplasia is an overgrowth of cells that is considered a marker for future breast cancer risk.) Researchers used four doses; the lower two used were equivalent to concentrations found in drinking water in fracking

regions and the highest dose represented concentrations that have been measured in industry wastewater. Mammary gland effects varied for each the doses, but all groups developed intraductal hyperplasia. According to a co-author, “This study shows that a mixture of [fracking] chemicals can affect the long-term health of the mouse mammary gland, even after low level exposures in the womb.”⁶²³

- January 15, 2018 – A study of urban oil drilling in two Los Angeles neighborhoods found elevated asthma rates among residents living within 1,500 feet of oil wells. Researchers compared diagnosed asthma rates in these areas to a representative comparison area (the California Health Interview Survey’s “SPA6” in South Los Angeles) and to Los Angeles County as a whole.⁶²⁴ The diagnosed asthma rates in the two study areas were statistically significantly higher (16.1 percent and 23.6 percent) than the comparison area (9.8 percent). Asthma prevalence in one of the two study areas was significantly higher than that in Los Angeles County as a whole. Households with smokers were excluded from the analysis. This interdisciplinary team worked in partnership with the local residents to conduct this community-based survey with limited resources and urged further studies with more complex scientific design.
- December 13, 2017 – A team of health economists analyzed fracking’s health impacts on infants. They examined birth certificates for all 1.1 million infants born in Pennsylvania between 2004 and 2013 and combined these data with maps showing when and where gas wells were drilled in the state. Their results indicated that the introduction of fracking “reduces health among infants born to mothers living within 3 km (1.9 miles) of a well site during pregnancy.” For mothers living within one kilometer (.6 miles), they found a 25 percent increase in the probability of low birth weight, “significant declines” in average birth weight, as well as declines in other measures of infant health. They also observed reductions in infant health when mothers lived within one to three kilometers of a fracking site; these were about one-third to one-half of the declines of those mothers living closer.⁶²⁵ The researchers estimated that “about 29,000 out of the nearly 4 million U.S. births (0.7 percent) annually occur within 1 kilometer of a fracking site and 95,500 are born within 3 kilometers.” “For policymakers weighing the costs and benefits of fracking before deciding whether to allow it in their communities, this study provides a clear cost: an increase in the probability of poorer health for babies born near these sites.”⁶²⁶

- November 6, 2017 – As part of a pilot project, a team of Montreal-based public health researchers evaluated exposure of pregnant mothers to VOCs in an area of intensive fracking in northeastern British Columbia. At least 28,000 unconventional natural gas wells had been drilled to date in the Peace River Valley. Analyzing the urine of 29 pregnant women, researchers found high concentrations of muconic acid, which is a degradation product of benzene, a widely studied developmental toxicant and an air contaminant in the vicinity of gas wells. The median concentration of this chemical was approximately 3.5 times higher in the study group than in the general Canadian population. In five of the 29 women, the concentration of muconic acid exceeded an exposure index by the American Conference of Governmental Industrial Hygienists that was designed for workplace settings. (No guidelines for the public exist.) By design, this small pilot study sets the groundwork for more extensive biomonitoring and environmental analysis.⁶²⁷
- September 19, 2017 – University of Texas Health Science Center researchers conducted a case-control study nested within their larger cohort of women with single births (see entry for July 21, 2017, below) in the 24-county Barnett Shale between November 30, 2010 and November 29, 2012. Its specific purpose was to consider timing of unconventional gas development activity “during potentially sensitive windows of exposure,” as well as “potential differences in risk by UGD drilling phase,” with regard to preterm births. Results suggest a link between maternal residential proximity to UGD-activity and preterm births, which were similar by drilling phase and “slightly stronger in the first two trimesters of pregnancy.”⁶²⁸
- September 14, 2017 – Researchers reviewed health assessments taken between February 2012 and October 2015 of adults in Pennsylvania communities with intense unconventional natural gas development (UNGD). The most frequently reported symptoms were sleep disturbance, headache, throat irritation, stress/anxiety, cough, shortness of breath, sinus problems, fatigue, wheezing, nausea, each occurring in over 20 percent of the sample. Over 43 percent of the sample reported sleep disturbance. To meet the inclusion criteria, as developed and implemented by a physician and nurse practitioner, the symptoms were reviewed to ensure no plausible cause relating to “past medical and surgical history, concurrent medical conditions, family and social history, and environmental exposures unrelated to UNGD. For example, if the social history indicated a ½ pack/day smoking history, the symptom of ‘difficulty breathing’ was not included.” Independently, the timing of the exposure for each symptom that met the inclusion criteria was determined, using the beginning drilling date for each unconventional natural gas well within one kilometer (.6 miles) of the patient’s residence;

records were excluded if it was not possible to verify at least one gas well within this distance.⁶²⁹

- August 21, 2017 – Using county-level data from 2003 to 2013, researchers found that, all together, counties in the Marcellus Shale region that experienced a boom in hydraulic fracturing showed a 20 percent increase in the incidence rate of gonorrhea.⁶³⁰
- July 21, 2017 – A University of Texas Health Science Center School of Public Health team assessed the links between the residential proximity of pregnant mothers to unconventional natural gas development activity and various newborn health problems: preterm birth, small-for-gestational age (SGA), fetal death, and low birth weight. They found evidence of a “moderate positive association” between residential proximity to UGD-activity and increased odds of preterm birth, and a “suggestive association” with fetal death. Nearly 159,000 births and fetal deaths from November 30, 2010 to November 29, 2012 in the 24-county Barnett Shale area were considered.⁶³¹
- February 15, 2017 – A study from the University of Colorado School of Public Health and Anschutz Medical Campus showed that children and young adults between the ages of 5 and 24 with acute lymphocytic leukemia (ALL) were 4.3 times more likely to live in area dense with active oil and gas wells. The researchers did not find such a link with ALL cases in 0-4 year olds, or with incidence of non-Hodgkin lymphoma. The study focused on rural areas and towns in 57 Colorado counties and did not include cities of more than 50,000 people. Authors wrote, “Because oil and gas development has potential to expose a large population to known hematologic carcinogens, such as benzene, further study is clearly needed to substantiate both our positive and negative findings.”⁶³²
- October 26, 2016 – A study that investigated possible links between fracking and cancer incidence in southwest Pennsylvania found elevated rates of bladder and thyroid cancers in six counties with shale gas activity.⁶³³ Bladder cancer was elevated in both males and females, with a 10 percent increase in the number of observed cases from 2000 to 2012. Over the same time period, thyroid cancer jumped even more dramatically. “There was a huge 91.2% increase in the number of observed cases from 2000 to 2012.” Patterns of leukemia incidence were less clearly related to shale gas activity. The author expressed caution in attributing these trends solely to shale gas development due to “the multiple

sources of potentially toxic, harmful exposures in southwest Pennsylvania, many dating back decades,” the long latency time required for many cancers to develop, and possible synergisms between exposures from shale gas development and past toxic exposures.

- August 25, 2016 – Researchers found that Pennsylvanians residing near intensive unconventional gas well activity were significantly more likely to experience chronic rhino sinusitis (at least three months of nasal and sinus symptoms), migraine headaches, and higher levels of fatigue than residents who do not live near such activity.⁶³⁴ Data were gathered from nearly 8,000 patients of Geisinger Health System from 40 counties in north and central Pennsylvania, and matched with the proximity of respondents to all phases of gas drilling activity and intensity, using information from the Pennsylvania Departments of Environmental Protection (PA DEP) and Conservation and Natural Resources, as well as satellite imagery. According to lead author Aaron W. Tustin, MD, MPH, resident physician in the Department of Environmental Health Sciences at the Johns Hopkins Bloomberg School of Public Health, “[t]hese three health conditions can have debilitating impacts on people’s lives... In addition, they cost the health care system a lot of money.”⁶³⁵
- July 18, 2016 – Living near fracking operations significantly increases asthma attacks, according to a Johns Hopkins University study of 35,000 medical records of people with asthma in north and central Pennsylvania, from 2005 to 2012.⁶³⁶ The data show that those who live near a higher number of, or larger, active gas wells were 1.5 to 4 times more likely to suffer from asthma attacks compared to those who live farther away, with the closest group having the highest risk. There was increased risk in all three types of exacerbations defined: mild (new oral corticosteroid medication order), moderate (emergency department encounter), or severe (hospitalization). In addition, researchers identified increased risk during all four phases of well development: pad preparation, drilling, stimulation (fracking), and production. The study was praised for its “rigorous research methods,” by a scientist not part of the team.⁶³⁷
- July 5, 2016 – Researchers from five universities and the U.S. Geological Survey (USGS) identified a link between exposure to fracking and drilling chemicals and adverse reproductive and developmental outcomes in laboratory mice. The study used 23 oil and gas chemicals in four different concentrations, representing concentrations found in drinking water and groundwater, to higher concentrations found in oil and gas industry

wastewater. Offspring of pregnant laboratory mice consuming these mixtures were compared to those that did not. Results suggested “numerous potential threats to fertility and reproductive success . . . including altered pituitary hormone levels, reproductive organ weights, and disrupted ovarian follicle development.” Researchers observed these negative outcomes even in the offspring exposed to the lowest dose of chemicals. Building on previous research showing reduced sperm counts in male offspring, they also reported on “tentative mechanistic information for the observed adverse health effects.”⁶³⁸

- February 9, 2016 – An exploratory study of hospitalization rates for three study areas in Queensland, Australia showed rates for specific types of hospital admissions increased more quickly in a coal seam gas study area than in other study areas (a coal mining area and a rural/agricultural area). Coal seam gas is the methane trapped in pores and fractures in underground coal deposits; its exploitation is a form of unconventional natural gas development. A portion of coal seam gas extraction uses fracking. This preliminary study found the strongest link between increased hospitalization rates over time in a coal seam gas area to be for the category of ‘Blood/immune’ diseases.⁶³⁹
- October 14, 2015 – Using an animal model, an interdisciplinary research team measured the endocrine-disrupting activities of 24 chemicals used and/or produced by oil and gas operations, finding that 23 of them “can activate or inhibit the estrogen, androgen, glucocorticoid, progesterone, and/or thyroid receptors, and mixtures of these chemicals can behave synergistically, additively, or antagonistically.” Further, the researchers tested prenatal exposures to the chemicals and found effects on multiple organs, including adverse reproductive effects on the matured offspring.⁶⁴⁰ This study is the first to demonstrate that endocrine-disrupting chemicals, which are commonly used in fracking operations, can harm the reproductive health of mice, at levels of exposure that are realistic for humans. The study’s senior author told *ScienceDaily*, “In addition to reduced sperm counts, the male mice exposed to the mixture of chemicals had elevated levels of testosterone in their blood and larger testicles. These findings may have implications for the fertility of men living in regions with dense oil and/or natural gas production.”⁶⁴¹
- October 8, 2015 – Pregnant women who live near active fracking operations in Pennsylvania were at a 40 percent increased risk of giving birth prematurely and at a 30 percent increased risk for having obstetrician-labeled high-risk pregnancies, according to a study by Johns Hopkins Bloomberg School of Public Health and other researchers.

High-risk pregnancies were those that included hypertension, high pre-pregnancy body mass index, and asthma. The study used data from the Geisinger Health System on 9,384 pregnant women and their 10,496 newborns between January 2009 and January 2013; Geisinger covers 40 counties in north and central Pennsylvania. Researchers developed an index for proximity to fracking wells based on distance from the women’s homes, stage of drilling and depth of wells dug, and the amount of gas that was produced at those wells during the pregnancies. The highest-activity quartile had the highest rates of premature births and high-risk pregnancies.^{642, 643}

- July 22, 2015 – Using a mammal model, New York University School of Medicine scientists, together with other U.S. and Chinese researchers, demonstrated cancerous changes linked to exposure to wastewater from Marcellus fracking operations. Their study also documented elevated levels of barium and strontium in exposed animal cells. The wastewater studied originated in Pennsylvania and was stored for a time to allow radioactivity and levels of short-lived VOCs to decline. The results suggest that “even aged flow back water could pose substantial health threats to exposed humans.”⁶⁴⁴
- July 15, 2015 – A study by University of Pennsylvania and Columbia University researchers found that drilling and fracking activity was associated with increased rates of hospitalization in Pennsylvania. During a period of dramatic increase in drilling and fracking activity between 2007 and 2011, inpatient prevalence rates surged for people living near shale gas wells. Cardiology inpatient prevalence rates were significantly associated with number of wells per zip code and their density, while neurology inpatient prevalence rates were significantly associated with density of wells. Hospitalizations for cancer, skin conditions, and urological problems also rose significantly. During the same time period, no such increase in health problems was observed in a control Pennsylvania county without any drilling and fracking activity. In communities with the most wells, the rate of cardiology hospitalizations was 27 percent higher than in control communities with no fracking. “While the clinical significance of the association remains to be shown, [fracking] has just begun in Pennsylvania, and thus observing a significant association over this short time is striking.... Our study also supports the concept that health care utilization should be factored into the value (costs and benefits) of hydraulic fracturing over time.”⁶⁴⁵ In a related *Newsweek* story, lead researcher Reynold Panettieri, Jr. said, “At this point, we suspect that residents are exposed to many toxicants, noise and social stressors due to hydraulic fracturing near their homes and this may add to the increased

number of hospitalizations.”⁶⁴⁶

- July 9, 2015 – As part of a scientific assessment of well stimulation treatments, including fracking, the California Council on Science and Technology studied the potential impacts of well stimulation on human health in California. The risk factors directly attributable to well stimulation stem largely from the use of a very large number and quantity of stimulation chemicals. The unknown number and toxicity of chemicals that are mixed together in well stimulation fluids made it difficult to fully quantify risk to the environment and to human health, but the study highlighted the potential health risks from exposure to fracking-related air pollution for the people of Los Angeles, 1.7 million of whom live or work within one mile of an active oil or gas well.⁶⁴⁷ Jane Long, co-author, said, “officials should fully understand the toxicity and environmental profiles of all chemicals before allowing them to be used in California's oil operations,” according to the *Los Angeles Times*.⁶⁴⁸
- June 22, 2015 – A longtime midwife reported her personal analysis of an ongoing spike in infant deaths, miscarriages, and placental abnormalities in Utah’s Uintah Basin that has followed the advent of drilling and fracking activity there and appears linked to air pollution episodes.⁶⁴⁹
- June 3, 2015 – A University of Pittsburgh study linked fracking to low birthweight in three heavily drilled Pennsylvania counties. The more exposure a pregnant woman had to gas wells, the higher her risk for a smaller-than-normal baby. Exposure was determined as proximity and density of wells in relation to the residence of the pregnant woman. Compared to mothers whose homes had the fewest surrounding gas wells, mothers whose homes were nearest to a high density of wells were 34 percent more likely to have babies who were “small for gestational age,” meaning they weighed significantly less than expected for the number of weeks of pregnancy. Although the study did not investigate mechanisms, researchers identified air as the likely route of exposure. They supported this argument by referencing another study done in Western Pennsylvania where airborne particulate pollution correlated with low birth weight and by noting that particulates are established shale gas infrastructure emissions.^{650, 651} Low birth weight is a leading cause

of infant mortality.

- March 3, 2015 – A follow-up study of 21 case studies from five states found that the distribution of symptoms in animals and humans affected by nearby fracking operations was, since 2012, unchanged for humans and companion animals. In food animals, reproductive problems decreased over time while respiratory problems and growth problems increased. “This longitudinal case study illustrates the importance of obtaining detailed epidemiological data on the long-term health effects of multiple chemical exposures and multiple routes of exposure that are characteristic of the environmental impacts of unconventional drilling operations.”⁶⁵²
- March 3, 2015 – A cross-sectional study by Yale University School of Medicine researchers using companion animals as sentinels of human exposure to fracking-related chemicals investigated possible associations between reported health conditions of companion and backyard animals in Southwest Pennsylvania and household proximity to drilling and fracking operations. Among dogs living in households located less than one kilometer from a gas well, risks for health problems were elevated, especially for dermal conditions, compared to animals living more than two kilometers from a well.⁶⁵³
- January 1, 2015 – A Yale-led team studied the relationship between household proximity to drilling and fracking operations and reported health symptoms in Washington County, Pennsylvania where 624 gas wells were in active operation, most of which had been drilled in the past five to six years. Researchers found that health symptoms reported by residents increased in frequency as distance between household and gas wells decreased. Among persons living less than one kilometer from drilling and fracking operations, rashes and upper respiratory problems were more prevalent. The authors of this study, the largest to date on the link between reported symptoms and natural gas drilling activities, say that their findings are “... consistent with earlier reports of respiratory and dermal conditions in persons living near natural gas wells.” They also cite literature demonstrating the biological plausibility of a link between oil and gas extraction activities and both categories of health effects reported.⁶⁵⁴

See also footnote 29.

Health (NYS DOH) identified environmental problems associated with fracking that could contribute to adverse public health impacts. Among them: air pollution (particulate matter, ozone, diesel exhaust, and VOCs) that could affect respiratory health; drinking water contamination from underground migration of methane and/or fracking chemicals associated with faulty well construction or seismic activity; drinking water contamination from inadequate water treatment of fracking waste or from surface spills of fracking chemicals or wastewater; earthquakes and the creation of fissures; increased vehicle traffic; increased noise; increased demand for housing and medical care; and public health problems related to climate change impacts from methane and other greenhouse gas emissions into the atmosphere. The NYS DOH Public Health Review also discussed findings from surveys of health symptoms among residents living near high volume hydraulic fracturing activities. These included skin rash, nausea or vomiting, abdominal pain, breathing difficulties, cough, nosebleed, anxiety, stress, headache, dizziness, eye irritation, and throat irritation in populations living near drilling and fracking operations. The NYS DOH Public Health Review noted that ongoing studies by both government agencies and several academic institutions were exploring the public health risks and impacts of fracking but that many of these studies were years from completion. The review concludes:

... significant gaps exist in the knowledge of potential public health impacts from [high volume hydraulic fracturing].... The existing science investigating associations between [high volume hydraulic fracturing] activities and observable adverse health outcomes is very sparse and the studies that have been published have significant scientific limitations. Nevertheless, studies are suggestive of potential public health risks related to [high volume hydraulic fracturing] activity that warrant further careful evaluation.

In an accompanying letter to the New York State Department of Environmental Conservation, Health Commissioner Howard Zucker, MD, concluded,

... the overall weight of the evidence from the cumulative body of information contained in this Public Health Review demonstrates that there are significant uncertainties about the kinds of adverse health outcomes that may be associated with [high volume hydraulic fracturing], the likelihood of the occurrence of adverse health outcomes and the effectiveness of some of the mitigation measures in reducing or preventing environmental impacts which could adversely affect public health. Until the science provides sufficient information to determine the level of risk to public health from [fracking] to all New Yorkers and whether the risks can be adequately managed, DOH recommends that high volume hydraulic fracturing should not proceed in NYS.⁶⁵⁵

- October 13, 2014 – According to the North Dakota Health Department, the number of HIV and AIDS cases in North Dakota more than doubled between 2012 and 2014, and

⁶⁵⁵ New York State Department of Health. (2014, December 17). *A public health review of high volume hydraulic fracturing for shale gas development*. Retrieved from http://www.health.ny.gov/press/reports/docs/high_volume_hydraulic_fracturing.pdf

cases were shifting to the state’s western oil fields, where 35-40 percent of all new cases occurred. Previously, only 10 percent of cases were in that region.⁶⁵⁶ This trend followed on the heels of an upsurge in sexually transmitted chlamydia cases in the same region. The North Dakota state director of disease control, Kirby Kruger, attributed the uptick in HIV cases to the drilling and fracking industry and attempted to spread HIV prevention messages at the “man camps” that house young male workers in the oil industry.⁶⁵⁷ Human trafficking for purposes of prostitution accompanied the fracking boom, but there was a shortage of medical professionals to address this public health crisis, according to Kruger, who noted that it was difficult to hire nurses and medical staff who could live in the area on a public health wage.

- October 2, 2014 – According to researchers from the University of Pennsylvania’s Center of Excellence in Environmental Toxicology, an increasing number of gas wells in Pennsylvania is significantly correlated with inpatient rates of hospitalization. The research team collected data from seven different insurance providers for three counties; the study’s publication is forthcoming.⁶⁵⁸
- September 11, 2014 – In Texas, commercial vehicle accidents have increased more than 50 percent since 2009 when the state’s ongoing drilling and fracking boom began, according to an investigation by the *Houston Chronicle* and Houston Public Media News 88.7. “For six decades, highway deaths have dropped steadily all across the United States... But in Texas all motor vehicle fatalities – and accidents involving commercial trucks – have turned back upward since the state’s oil drilling and fracking boom began in 2008.” This rising motor vehicle death toll is especially felt in formerly rural counties in the Eagle Ford and Permian Basin, now places of heavy drilling and fracking. A new Department of Public Safety “Road Check” program finds annually, “27 to 30 percent of Texas’ commercial trucks shouldn’t be operating at all due to potentially life-threatening safety problems like defective brakes, bald tires, inoperable safety lights and unqualified, unfit or intoxicated drivers.”^{659, 660}
- August 3, 2014 – Hospitals in the Bakken Shale region reported a sharp rise in ambulance calls and emergency room visits after 2006. “Mercy Medical Center in Williston and the Tioga Medical Center in neighboring Williams County saw their ambulance runs increase by more than 200 percent. Tioga’s hospital saw a staggering leap in trauma patients by 1,125 percent. Mercy had a 373 percent increase.” Drugs (including overdoses of

prescription drugs, methamphetamine, and heroin) explain many of the cases, with oilfield related injuries such as “fingers crushed or cut off, extremity injuries, burns and pressure burns” accounting for 50 percent of the cases in one of the region’s hospital emergency rooms.⁶⁶¹

- May 21, 2014 – Raising questions about possible links to worsening air pollution from the Uintah Basin’s 11,200 oil and gas wells, health professionals reported that infant deaths in Vernal, Utah, rose to six times the normal rate over the past three years. Physician Brian Moench said, “We know that pregnant women who breathe more air pollution have much higher rates of virtually every adverse pregnancy outcome that exists.... And we know that this particular town is the center of an oil and gas boom that’s been going on for the past five or six years and has uniquely high particulate matter and high ozone.”⁶⁶² Although it formerly had pristine air quality, Uintah County, Utah received a grade “F” for ozone in the American Lung Association’s 2013 State of the Air Report.⁶⁶³
- January 28, 2014 – Congenital heart defects, and possibly neural tube defects in newborns, were associated with the density and proximity of natural gas wells within a 10-mile radius of mothers’ residences in a study of almost 25,000 births from 1996 to 2009 in rural Colorado. The researchers note that natural gas development emits several chemicals known to increase risk of birth defects (teratogens).⁶⁶⁴
- January 4, 2014 – Preliminary data from researchers at Princeton University, Columbia University, and MIT showed elevated rates of low birthweight among infants born to mothers living near drilling and fracking operations during their pregnancies.⁶⁶⁵
- October 2013 – A preliminary study of the health impacts of oil and gas extraction on infant health in Colorado found that proximity to wells—linked with air pollutants from fracking operations—was associated with reductions in average birthweight and length of pregnancy as well as increased risk for low birthweight and premature birth.⁶⁶⁶ A study by the same author, currently under review, which analyzed births to Pennsylvania mothers residing close to a shale gas well in Pennsylvania from 2003 to 2010, also identified increased risk of adverse effects. This includes low birth weight, as well as a 26 percent increase in APGAR scores under 8. (APGAR—or American Pediatric Gross

Assessment Record—is a measure of newborn responsiveness. Scores of less than 8 predict an increase in the need for respiratory support.)⁶⁶⁷ (See entry above for August 13, 2018.)

- August 26, 2013 – Medical experts at a rural clinic in heavily-drilled Washington County, Pennsylvania reported case studies of 20 individuals with acute symptoms consistent with exposure to air contaminants known to be emitted from local fracking operations.^{668, 669}
- May 2, 2013 – A community-based participatory research study in Pennsylvania tested air and water quality and surveyed self-reported health symptoms of more than 100 residents living near drilling and fracking operations. The team detected a total of 19 VOCs in ambient air sampled outside of homes. The reported health symptoms closely matched the established effects of chemicals detected through air and water testing at those nearby sites. Moreover, those symptoms occurred at significantly higher rates in households closer to the gas facilities than those farther away.⁶⁷⁰ Indicative of the growing prevalence of such health impacts in the state, a poll showed that two-thirds of Pennsylvanians support a moratorium on fracking because of concern about negative health impacts.⁶⁷¹

Noise pollution, light pollution, and stress

Drilling and fracking operations and ancillary infrastructure expose workers and nearby residents to continuous noise and light pollution that is sustained for periods lasting many months. Chronic exposure to light at night is linked to adverse health effects, including breast cancer. Sources of fracking-related noise pollution include blasting, drilling, flaring, generators, compressor stations, and truck traffic. Exposure to environmental noise pollution is linked to cardiovascular disease, cognitive impairment, and sleep disturbance. In Colorado, noise measured during construction and drilling of a large, multi-well pad in a residential area exceeded levels known to increase the risk of cardiovascular diseases and hypertension. In rural Canada, residents living near drilling and fracking operations experienced community upheaval and showed multiple signs of trauma. Oil and gas production noise may be disrupting wildlife health in protected areas. Workers and residents whose homes, schools, and workplaces are in close proximity to well sites are at risk from these exposures as well as from related stressors. Existing “setback distances” may not be adequate to reduce public health threats, especially for vulnerable populations. A UK Health Impact Assessment (HIA) identified stress and anxiety resulting from drilling-related noise—as well as from a sense of uncertainty about the future and eroded public trust—as key public health risks related to fracking operations.

- October 8, 2018 – Researchers collected noise measurements from residential areas, inside and outside homes, near two different gas well pads and a compressor station, north and south of Pittsburgh, Pennsylvania. Measurements from all of the outside areas had at least some decibel levels exceeding the recommended limits of the U.S. Environmental Protection Agency (EPA), and one indoor measurement near the compressor station exceeded the recommended level for noise measured inside homes. An accompanying survey documented that 96 percent of respondents were “worried about their overall health as a result of the noise.” Fifty-seven percent were bothered “a great deal” by the noise, and slightly more than half of respondents said that their sleep was disturbed “a great deal” by the noise.⁶⁷²
- October 4, 2018 – In the month following one or more earthquakes greater than magnitude 4 experienced in an Oklahoma county, motor vehicle crashes increased 4.6 percent. Anxiety-inducing life events increase the risk of motor vehicle crashes, and earthquakes are known to increase anxiety. University of California, Berkeley public health researchers used data on Oklahoma earthquakes between 2010 and 2016, known to have drastically increased in the state due to fracking wastewater injection, and county-level monthly vehicle crash counts. Authors noted “the high economic and social costs of such vehicle crashes,” which were \$2.9 billion in Oklahoma in 2010.⁶⁷³

⁶⁷³ Casey, J. A., Elser, H., Goldman-Mellor, S., & Catalano, R. (2018). Increased motor vehicle crashes following induced earthquakes in Oklahoma, USA. *Science of the Total Environment, 650*, 2974-2979. doi: 10.1016/j.scitotenv.2018.10.043

- May 30, 2018 – Anxiety-related Google searches increased 5.8 percent during months when there was more than one magnitude 4 or higher earthquake experienced in Oklahoma, from January 2010 to May 2017. Google searches for anxiety peaked three weeks after magnitude 4 or higher quakes, University of California, Berkeley public health researchers found. Oil and gas wastewater injection has dramatically increased seismicity in Oklahoma; in the study period, there were 8,908 earthquakes across the state of Oklahoma, an average of 218 earthquakes per month. Authors noted, “excessive anxiety... may disable individuals and has long-term implications for health and functioning,” and that “excessive symptoms of anxiety occur more readily in response to a recurrent and unpredictable stressor, such as the Oklahoma earthquakes included in our study.”⁶⁷⁴
- May 11, 2018 – Over 40 percent of daytime and 23.6 percent of nighttime audible noise measurements taken during construction and drilling of a large, multi-well pad in a residential area were found to exceed the level that research has demonstrated to increase the risk of health effects, such as cardiovascular diseases and hypertension. When the researchers used an additional measurement that captures low frequency noise levels, these results showed that 97.5 percent of daytime and 98.3 percent of nighttime measurements exceeded the level “recommended to minimize impacts such as nausea and headaches.” The measurements collected during this study were from four locations, over three months, in residential areas with oil and gas development in Colorado. Researchers concluded that the distances from the well pad at which some of their measurements were taken, highlight “that homes in closer proximity to operations will likely experience noise exposure at levels of concern even with the implementation of sound mitigation best management practices.”⁶⁷⁵
- December 29, 2017 – Every participant reported experiencing effects in one or more of five categories—psychological stress, social stress, environment, physical health, and traffic—in a study of how residents of two adjacent counties in Ohio are impacted by unconventional natural gas development. Most respondents reported impacts in three or more of the five categories. Types of psychological stress reported included general stress and uncertainty about the future; feeling frustrated and manipulated after interactions with the oil and gas industry; experiencing stress from noise or light pollution; and regional displacement. Researchers found that experiences of social stress extended to include divisions among family or community; fears of, or direct experiences of, environmental health harms; observing dying, unhealthy trees; and traffic-related effects. Nearly all residents interviewed had experienced dangerous encounters with oil and gas truck drivers and observed that damaged roads had become increasingly common.⁶⁷⁶

Advance online publication. doi: 10.1016/j.jenvp.2017.12.008

- July 28, 2017 – A Canadian case study of the social impacts of fracking in a conservative, upper middle class, rural region of southern Alberta found that residents experienced “complete upheaval in their beliefs, and for many, their experiences with contamination, and fears of future exposure, dominate their lives.”⁶⁷⁷ Participants described acute impacts to their own health, to family members’ health, to their livestock (including fertility problems), and to their land (included disrupted crop production and abrupt changes to the landscape). The study further reported that authorities failed to respond, “in a manner expected by the victims” to these problems. In addition, “corrosion of community” occurred at a time when victims needed community support the most. The author posited, following a consideration of the literature on toxic contamination and trauma, that her interviewees had experienced the three key indications of trauma: loss of agency, hyperarousal, and ontological insecurity linked to the negative effects on normal daily routines, a sense of order and continuity, and human dignity. The author noted that the contamination experienced by the interviewees reflected a “new normal of non-conventional fossil fuel industries.”
- May 5, 2017 – Oil and gas production was one of the main anthropogenic noise sources (though the proportion for which it was responsible was not determined) in a study that quantified the degree and extent of noise pollution in U.S. protected areas (PAs) and critical habitat for endangered species. Authors “compared noise pollution among land management and protection status and investigated sources responsible for generating noise across PAs.” The team of biologists and engineers found that human-caused noise doubled background sound in 63 percent of U.S. protected areas, and produced a tenfold or greater increase in 21 percent of protected areas. These levels are “known to interfere with human visitor experience and disrupt wildlife behavior, fitness, and community composition.” Researchers also found a 10-fold increase in sound levels in 14 percent of critical habitats of endangered species.⁶⁷⁸
- April 3, 2017 – A University of Maryland team conducted a pilot study of noise pollution at eight homes located less than a half mile (750 meters) from natural gas compressor stations in West Virginia and compared decibel levels to those collected from homes located further away. They found that daytime and nighttime noise levels were higher at properties located closer to a compressor, as measured both inside and outside the homes. Five of six homes that were monitored for a full 24-hour period had combined day-night indoor average noise levels that exceed 60 decibels (dBA), which exceeds both EPA’s recommended limits for chronic noise exposure as well those recommended by the World Health Organization. To date, no federal noise standards exist for oil and gas operations. Noting that noise exposure has been associated in previous studies with sleep disruption, poor academic performance, and hypertension, the authors conclude, “Findings indicate that living near natural gas compressor stations could potentially result

in high environmental noise exposures. Larger studies are needed to confirm these findings and evaluate potential health impacts and protections measures.”⁶⁷⁹

- December 9, 2016 – A review analyzing the relevant scientific literature on the potential public health impacts of ambient noise related to unconventional oil and gas development found that “oil and gas activities produce noise at levels that may increase the risk of adverse health outcomes, including annoyance, sleep disturbance, and cardiovascular disease.” The team of environmental and occupational health scientists collected available measurements of noise levels at oil and gas operations and analyzed the data with established noise standards. Authors stated that many noise sources from fracking operations are similar to those of conventional oil and gas development, but that high-volume hydraulic fracturing activities present additional noise risks. These arise from conditions including four to five times the length of time needed to drill the well, and the much greater volume of water and higher pressures needed, compared to a traditional vertical well. They described the complexity of noise associated with oil and gas operations, including both intermittent and continuous noise, varying in intensities. The review included focus on vulnerable populations, including children, the elderly, and the chronically ill. Authors noted that existing “setback distances” – already often the result of political compromise and not evidence-based – may be insufficient to reduce public health threats, and that maximum allowable noise levels should be lower for schools and hospitals.⁶⁸⁰
- July 9, 2015 – As part of its assessment of potential health impacts, the California Council of Science and Technology looked at the impacts of noise and light pollution from oil and gas operations in California. The researchers noted that a number of activities associated with drilling and fracking generated noise at levels considered dangerous to public health. Noise is a biological stressor that can aggravate or contribute to the development of hypertension and heart problems. In California, noise from well stimulation was associated with both sleep disturbance and cardiovascular disease in a dose-response relationship. Exposure to artificial light at night has been linked to breast cancer in women, although almost no research has been conducted on the public health implications of light pollution from oil and gas extraction specifically.⁶⁸¹
- December 17, 2014 – The New York State Department of Health (NYS DOH) identified community impacts related to noise as a potential contributor to a variety of negative health impacts from drilling and fracking operations but noted that considerable scientific uncertainty remains on the issue of noise exposure per se as a risk factor. Noise, air

pollution, traffic, vibration, odors, and nighttime lighting may all increase together as proximity to a drilling site decreases.⁶⁸²

- December 1, 2014 – Range Resources Corporation warned supervisors in Pennsylvania’s Donegal Township that a “big burn” natural gas flare will continue for as long as a week and “will produce a continuous noise of as much as 95 decibels at the well pad. Sustained decibel levels between 90 and 95 can result in permanent hearing loss, but workers will be equipped with ear protection.” Township supervisor Doug Teagarden expressed concern for residents, saying, “They told us the flare would be double the size of other well flares, and the noise will be like a siren on a firetruck.... There are houses within a couple of hundred yards of the well pad, and those folks are going to hear it.”⁶⁸³
- November 6, 2014 – Sakthi Karunanithi, Director of Public Health in Lancashire, UK, reported on a Health Impact Assessment (HIA) of the two proposed shale gas exploration sites in Lancashire. Karunanithi’s study determined that key risks to the health and well-being of the residents who live near the two proposed sites in Lancashire include stress and anxiety from uncertainty that could lead to “poor mental wellbeing,” and noise-related health effects due to continuous drilling. The HIA also noted a lack of public trust and confidence.^{684, 685}
- September 2014 – The Ohio Shale Country Listening Project, a collaborative effort to solicit, summarize, and share the perspectives and observations of those directly experiencing the shale gas build out in eastern Ohio, found that the more shale gas wells a community has, the less popular the oil and gas industry becomes. Many residents reported that they had not experienced the economic benefits promised by the oil and gas industry. They complained of increased rents and costs of gas and groceries, an influx of out-of-state workers, more vehicular accidents, road destruction from large trucks, and damaged landscape and cropland. Locals reported feeling less secure and more financially strapped.⁶⁸⁶

- June 20, 2014 – In its discussion of “Oil and Gas Drilling/Development Impacts,” the U.S. Office of Indian Energy and Economic Development detailed noise pollution from bulldozers, drill rigs, diesel engines, vehicular traffic, blasting, and flaring of gas. “If noise-producing activities occur near a residential area, noise levels from blasting, drilling, and other activities could exceed the U.S. Environmental Protection Agency (EPA) guidelines. The movement of heavy vehicles and drilling could result in frequent-to-continuous noise.... Drilling noise would occur continuously for 24 hours per day for one to two months or more depending on the depth of the formation.”⁶⁸⁷ Exposure to chronic noise can be deadly. The World Health Organization has documented the connection between environmental noise and health effects, including cardiovascular disease, cognitive impairment, sleep disturbance, and tinnitus. At least one million “healthy life years” are lost every year from traffic-related noise in the western part of Europe.⁶⁸⁸
- February 24, 2014 – In a review of the health effects from unconventional gas extraction published in the journal *Environmental Science & Technology*, leading researchers noted, “Noise exposure is a significant hazard due to the presence of multiple sources, including heavy equipment, compressors, and diesel powered generators. Loud continuous noise has health effects in working populations. It is likely that exposure to noise is substantial for many workers, and this is potentially important for health because drilling and servicing operations are exempt from some sections of the Occupational Safety and Health Administration noise standard.” They noted that research should investigate stressors such as noise and light in the context of drilling and fracking operations in order to understand the overall effect of chemical and physical stressors together.⁶⁸⁹
- May 30, 2014 – The *Denver Post* reported that in order to help meet Colorado’s noise limits for fracking operations in suburban neighborhoods (and partially block the glare of floodlights), Encana Oil and Gas erected 4-inch-thick polyvinyl walls up to 32 feet high and 800 feet long. Residents said that the plastic walls do not completely solve the problem.⁶⁹⁰
- October 25, 2013 – An analysis of well location and census data by the *Wall Street Journal* revealed that at least 15.3 million Americans now live within a mile of a well that has been drilled since 2000. According to this investigation, the fracking boom has ushered in “unprecedented industrialization” of communities across wide swaths of the

nation and, with it, “24/7” industrial noise, stadium lighting, earth-moving equipment, and truck traffic.⁶⁹¹

- April 16, 2013 – In a presentation on oil field light pollution for a conference on “Sustainable Environment and Energy: Searching for Synergies,” Roland Dechesne of the Royal Astronomical Society of Canada described problems of “light trespass,” glare, and poorly-aimed fixtures in oil fields in Alberta. He described resulting “mass waterfowl mortality” linked to artificial illumination and other biochemical impacts of light pollution on wildlife, as well as the possibility of these effects on humans, including circadian disruption, melatonin suppression, and possible resulting hormonally-linked diseases.⁶⁹² Known to have ecological impacts, outdoor light pollution from drilling and fracking operations may also be linked to artificial light-associated health effects documented in humans, including breast cancer.⁶⁹³
- April 2013 – Led by the University of Pittsburgh Graduate School of Public Health, a study of community members living in proximity to Marcellus Shale drilling in Pennsylvania found adverse impacts to mental health, with stress the most frequently reported symptom. At least half of all respondents in each set of interviews reported these specific stressors, including: being taken advantage of; health concerns; concerns/complaints ignored; corruption; denied information or provided with false information. Many also reported the desire to move or leave community, estrangement from community, and financial damages. Researchers noted that stress can result in direct health impacts.⁶⁹⁴ Notably, mounting evidence indicates that chronic stress magnifies individuals’ susceptibility to effects of pollution; for children, this interactive effect can begin during prenatal life.⁶⁹⁵
- September 7, 2011 – A study by researchers at Boise State University and Colorado State University at Fort Collins modeled the potential impacts of compressor station noise from oil and gas operations on Mesa Verde National Park in Colorado. The study found the sound of 64 compressors outside Mesa Verde elevated the sound level within the park by 34.8 decibels on average, and by 56.8 decibels on the side of the park located closest to

Earthquakes and seismic activity

Definitive evidence from Ohio, Arkansas, Texas, Oklahoma, Kansas, and Colorado links fracking wastewater disposal wells to earthquakes of magnitudes as high as 5.8, in addition to swarms of minor earthquakes. Both the U.S. Geological Survey (USGS) and state geological agencies such as the Oklahoma Geological Survey now acknowledge that earthquakes can be caused by wastewater injection into disposal wells. Many recent studies focus on the mechanical ability of pressurized fluids to trigger seismic activity by unclamping stressed faults. In some cases, and especially in Canada, Oklahoma, Ohio, and China, the fracking process itself has been linked to earthquakes. Emerging evidence suggests that risk of earthquakes can continue to rise for years after waste injection and cannot be prevented through “proper” fracking protocols or by solely limiting the rate or volume of injected fluid. Injecting fracking waste into shallower zones is one method for reducing earthquake risk, but shallow injection raises the risk for groundwater contamination. The question of what to do with fracking wastewater remains a problem with no viable, safe solution.

- March 27, 2019 – The USGS deployed additional seismometers in the area around south Alabama and the Florida Panhandle following the detection of five earthquakes in the course of a week. The earthquakes, ranging in magnitude from 2.1 to 3.7, occurred in an area flagged as likely experiencing more seismic activity over the past decade due to oil and gas operations in the area.⁶⁹⁷ In 1997, a series of earthquakes, including the second largest in Alabama’s history (at magnitude 4.9), occurred in the same region and was tentatively linked to oil and gas drilling and two associated injection wells nearby.⁶⁹⁸
- March 8, 2019 – Over a two-day period in February 2019, three earthquakes struck a farming community in an area of China’s Sichuan Province that is experiencing a fracking boom. Two people were killed, 13 injured, 20,000 homes destroyed, and 1,600 people displaced. In response to citizen protests, fracking operations were suspended.⁶⁹⁹
- March 1, 2019 – A USGS-led team monitored leakage and fluid pressure over time in a permeable bedrock formation used for disposal of fracking waste in Osage County, Oklahoma. By inserting specially designed instruments into an unused disposal well within this formation, the team demonstrated an overall trend of increasing fluid pressure. “The only conceivable source of this increase is due to the injection of wastewater.” The results also showed evidence that fracking waste is leaking out of the reservoir where it is being injected “at a significant rate.” The direction of the leakage appears mostly downward into the basement rock below. The authors note that disposal of fracking waste

is the leading cause of pressure changes on faults in Oklahoma and that fluid pressure changes are, in turn, the leading cause of earthquakes in Oklahoma.⁷⁰⁰

- December 12, 2018 – For six continuous years, hydraulic fracturing and related activities have triggered multiple earthquakes of varying magnitudes in northwestern Alberta and northeastern British Columbia, with the operations of one company linked to tremors that have jolted Fort St. John from 2012 to 2018.⁷⁰¹ Between September 2013 and January 2015 alone, researchers in western Alberta, Canada detected than 900 seismic events, ranging in magnitude from 1 to 4. Real-time recordings of seismic activity were generally consistent with published empirical and point-source simulation models. Approximately 80 percent of the events in the compiled database occurred “in distinct clusters in time and space that are characteristic of induced events.”⁷⁰² These induced earthquakes pose hazards to roads, pipelines, dams, groundwater, and public safety. Canadian scientists question whether any regulatory system could effectively forecast, control, or prevent them. In some cases, cessation of injection activities following large, potentially damaging earthquakes appears to a sufficient response. However, in other cases, quakes occur months after injection activities, falling outside the windows of immediate intervention that most “traffic light systems” are put in place to address.⁷⁰³ Further, companies are allowed to continue their activities despite predictions that considerable seismic activity may result, including earthquakes of much greater magnitude than predicted.⁷⁰⁴
- November 28, 2018 – Noting that fracking is a microseismic event, a research team investigated whether the activity of hydraulic fracturing itself, and not just the disposal of fracking waste, can trigger earthquakes and might be contributing to the dramatic increases in frequency of seismic events across the central and eastern United States. The team focused on Oklahoma where they identified roughly 700 fracking-induced earthquakes, including 12 with magnitude between 3 and 3.5. Previous reports had described only two fracking-induced earthquakes in Oklahoma. Results also confirmed that, in Oklahoma, proximity of an injection site to a critically stressed fault is a better predictor of induced seismicity than a more commonly accepted general approach based on proximity to the Precambrian basement layer. These results demonstrate that public research provides far greater detail and accuracy than data and notifications voluntarily released by drilling operators.⁷⁰⁵

- November 11, 2018 – In Lancashire, England, fracking has triggered at least 37 minor earthquakes. Regulations require suspension of fracking activities when seismicity exceeds magnitude 0.5. Energy company Cuadrilla, which had previously supported these limits, lobbied the government to relax the regulations in order to allow fracking to continue. These calls have been rejected by the energy minister.⁷⁰⁶
- October 31, 2018 – A holistic analysis of fracking waste disposal practices and seismicity compared intensely drilled regions across the United States, including the Bakken, Eagle Ford, and Permian shale basins, as well as basins in Oklahoma. Results showed consistent links between increased seismicity and increased depth of wastewater injection, increased rate of injection, and increased regional injection volumes. Shallower disposal wells help lower the risk of earthquakes. However, they raise the risk of groundwater contamination as increased pressures can push fluids through “faults or fractures or through abandoned oil wells that have not been properly plugged.” The researchers also noted that deep waste disposal carries the risk of introducing toxic fluids into karstified areas where there is “limited geologic characterization of the disposal zone.” These deep, cave-like zones may transmit fluids in an unknown, unpredictable fashion.⁷⁰⁷
- August 31, 2018 – To delineate possible mechanisms for the induction of earthquakes at unexpectedly large distances from injection wells, researchers looked at data in the public domain from around the world. They found two patterns. One type of seismicity, manifesting a “direct pressure effect,” clusters near wells and tends to be shallow, of modest magnitude, and to decay abruptly. The second type of seismicity, potentially triggered by elastic stresses, tends to occur in deeper layers, decay slowly, and exhibit larger spatial footprints and magnitudes. Both shallow and deep formations present unique risks, and these should be included in mitigation strategies.⁷⁰⁸ With low to moderate-sized human-made earthquakes putting 1 in 50 people in the United States at risk according to a recent USGS analysis, injection practices for oil and gas wastewater are “creating a ripple effect far beyond ... drilling locations.”⁷⁰⁹
- April 27, 2018 – The use of fracking to enhance geothermal energy recovery activated two faults in a previously unknown fault system and triggered a magnitude 5.5 earthquake near Pohang, South Korea. Using primarily publicly available data, the researchers characterized the fault dimensions, faulting mechanism, and depth of

earthquake activity, which correlated with surface deformation at the time of the earthquake activity. The earthquake's main shock caused extensive structural damage to buildings in and around Pohang and injured 70 people.⁷¹⁰

- March 16, 2018 – Utilizing satellite radar imagery, researchers observed and analyzed ground deformation, earthquake activity, and subsidence (depressions and sinkholes) that appear to be the result of “decades of oil activity and its effects on rocks below the earth's surface.”^{711, 712} Noting that West Texas has been “punctured like a pincushion with oil wells and injection wells since the 1940s,” the team documented an “alarming rate” of heaving and sinking across a 4,000-square-mile area.⁷¹³ The researchers documented visible surface-level and subsurface changes from fracking, fracking waste injection, carbon dioxide injection that is used to aid in oil and gas extraction, and abandoned and uncapped wells. Some data may help sort out why hazards manifest in one site rather than another. Satellite assessments of deformation can provide crucial safety information to protect roadways, homes, businesses, industrial facilities, pipelines, and people from “potential larger catastrophic events.”
- February 27, 2018 – Since December 2016 in Oklahoma, 74 earthquakes of at least 2.5 magnitude have been linked directly to fracking. As a result, state regulators tightened mitigation protocols and required operators to use seismic arrays to detect underground movement and pause their work when earthquakes exceed magnitude 2.5.⁷¹⁴ These changes make Oklahoma's new regulations tougher than Canada's, where “the industry holds the record for causing magnitude 4-plus earthquakes by high volume fracking.”⁷¹⁵ Described by industry sources as “a cautious move forward, limiting though not hamstringing [the] oil industry,” the new regulations will be evaluated in the field for their effectiveness in reducing the frequency of earthquakes large enough to be felt at the surface.⁷¹⁶

- February 20, 2018 – Researchers in Kansas used high-precision data from an extensive seismometer network to detail features of a surge of earthquakes that they concluded were induced by wastewater injection in southern Kansas. Some areas were free from earthquakes, despite injection activities, suggesting that unknown local geological conditions play a role in determining seismic activity. Lack of seismic activity in these areas is “either due to a lack of fluid pathways to the basement [deep geological layer] or due to the absence of faults that are close to failing.” Regional influences led to more prolonged seismicity and were observed from wastewater injection wells located 10 or more kilometers away.⁷¹⁷
- February 15, 2018 – In Kansas, swarms of earthquakes near oil wastewater disposal wells began in 2013. By 2017, the prodigious volumes of injected fluid created sufficient pressure to trigger earthquakes more than 50 miles away and form a “triggering front” that advanced at an average rate of nearly 10 miles per year along a permeable fault zone.⁷¹⁸ A mapping project based on gravity loads, magnetic fields, and seismic activity dating to 1979 revealed a previously unidentified subsurface fault running from central Nebraska 200 miles southeast to Kansas.⁷¹⁹
- February 5, 2018 – Focusing their investigation on areas in Ohio that are isolated from fracking waste injection activities, researchers found that fracking itself induced earthquakes in two distinct manners. In some cases, earthquake activity occurred in shallow subsurface layers and was of short duration and small magnitude. In other, more troubling cases, earthquakes were more powerful and took place in very deep layers, far below the layers being fracked, even when fracking did not directly contact faults in the basement rock. At three of five sites, earthquake activity continued for over a month after fracking activities ceased. These results support a causal role for poroelastic stress, sometimes operating over long distances, in addition to more predictable pore fluid pressure changes, in the generation of earthquakes by fracking.^{720, 721}
- January 19, 2018 – Some of the largest earthquakes related to fracking have occurred near Fox Creek, Alberta, in Canada. Using publicly available data, researchers studied earthquakes induced both by fracking waste injection and by hydraulic fracturing itself. In both cases, the volume of fluid injected, rather than injection rate or injection pressure,

was most strongly correlated with seismic activity. Geologic factors also played a role, with earthquakes more likely if fracking and disposal activities were conducted closer to faulting and areas of stress. Combining injected volume with geologic factors, researchers developed a model that can predict 96 percent of the seismic variability in the region, improving hazard estimations. Calculating a “seismogenic activation potential,” particularly if coupled with microseismic monitoring in real time to detect previously unknown faulting, may improve earthquake forecasting.⁷²²

- November 24, 2017 – A team of geologists confirmed conclusively that recent earthquakes in Texas’ Fort Worth Basin were induced by underground injection of fracking waste that caused deep, critically stressed faults to slip.⁷²³ The authors of this study employed a classical structural geology analysis that relied on high-resolution seismic reflection imaging, described in an interview with geophysical researcher Maria Magnani as “a little bit like an ultrasound.”⁷²⁴ Maps of the seismically active faults in the Fort Worth Basin show no evidence of previous motion over the past millions of years and instead have been “sleeping” for approximately the past 300 million years until “awakened” at the start of the 2008 earthquake swarm associated temporally with extensive wastewater injection activities.⁷²⁵
- October 21, 2017 – Extending the findings of two previous studies, an investigation of earthquakes in the Raton Basin along the border of New Mexico and Colorado identified wastewater injection wells as the cause of the quakes and identified a mechanism.⁷²⁶ All together, the location of the earthquakes, modeled pore pressures, and the direct correlation between cumulative volume of injected waste in nearby wells and the number of quakes show that seismicity in the Raton Basin is likely induced, and that elevated pore pressures deep underground are “well above earthquake-triggering thresholds.”⁷²⁷

seismic considerations in mind, nor are there seismic regulations in place for its 250,000-barrel oil tanks, which are under the purview of the Department of Transportation's Pipeline and Hazardous Materials Safety Administration. Central Oklahoma, where Cushing is located, became seismically active about five years ago when "wastewater injection and other fracking-related activities changed the seismic face of Oklahoma in dramatic fashion."⁷²⁸ (See also entry below for November 8, 2016.)

- August 11, 2017 – Using multiple lines of evidence, researchers in China determined that a series of high-magnitude earthquakes between 2014 and 2017 in Sichuan Basin was triggered by fracking activities that re-activated pre-existing faults. "The present study shows that short-term injections (continuing over several months) for shale gas hydraulic fracturing are ... very likely to induce M_w 4–5 class earthquakes in sites with similar geological and tectonic conditions within the southern Sichuan Basin."⁷²⁹
- May 3, 2017 – Studying two patterns of fracking waste injection in Oklahoma, geologists observed a large, unexpected impact on seismic activity at sites where injection rates drastically changed in recent years, as compared with those whose injection volumes held steady. They demonstrated that, in addition to direct pore pressure effects, deformations due to fluid flows ("poroelastic effects") play an important role in generating earthquake activity. Elevated risks for earthquakes can persist years after fracking waste is injected underground. Their findings also showed that the "magnitude of the initial change in injection rate is particularly important, but the opposite effect occurs in the transition to zero injection" (i.e., shut-in or closing a well). This result implies that "in certain faulting regimes it is theoretically possible to mitigate damaging effects of rapid shut-in by carefully tapering injection rates."⁷³⁰ Geophysicist Andrew Barbour, lead author of the study, said that fluctuating injection rates likely have a "profound effect" on earthquake risk.⁷³¹ These findings suggest that the 2016 Pawnee earthquake, the strongest earthquake ever recorded in Oklahoma, may have been triggered by pulses of underground oil and gas activity years earlier.⁷³²
- April 27, 2017 – Recognizing that increased seismicity from both hydraulic fracturing and underground disposal of fracking wastewater poses a hazard to critical infrastructure, such as large dams, a Canadian geologist proposed strategies to keep the likelihood of

high-failure consequences under one per ten thousand per year.⁷³³ The primary strategy is the creation of “no frack” exclusion zones with a 5-kilometer (3.1 mile) radius that would surround vulnerable, critical facilities. In a larger ring beyond the exclusion zone, to approximately 25 kilometers (15.5 miles), monitoring and response protocols would be used.⁷³⁴

- March 1, 2017 – Despite decreases of up to 40 percent in the volume of fracking wastewater injected underground in Oklahoma, researchers from the USGS Earthquake Hazard Program forecasted that seismic hazards would remain significantly elevated there throughout 2017, with the odds of damage from induced earthquakes within the next year “similar to that of natural earthquakes in high-hazard areas of California.” About three million people in Oklahoma and southern Kansas now live with continuing increased potential for damaging shaking from induced seismicity.”⁷³⁵ According to Mark Petersen, chief of the USGS National Seismic Hazard Mapping Project, the hazard risk remains “hundreds of times higher than before man-made activity began.”⁷³⁶
- February 17, 2017 – Pennsylvania’s Department of Environment Protection (PA DEP) announced that a series of small earthquakes in Lawrence County had been induced by fracturing of wells in the Utica Shale.⁷³⁷ PA DEP officials held a webinar to discuss the situation and formulate “procedures to reduce seismic risk going forward,” but no formal report or regulatory changes have yet been made public.⁷³⁸
- December 20, 2016 – In an attempt to reduced the risk of earthquakes caused directly by fracking, the Oklahoma Corporation Commission’s Oil and Gas Conservation Division introduced monitoring and response guidelines that include provisions requiring oil producers to “implement mitigation plans following an earthquake of magnitude 2.5 or more and to suspend operations following a quake of magnitude 3.5 or greater.”⁷³⁹

seismically quiescent. The researchers demonstrated that new earthquake activity in the Fox Creek area was tightly spatially correlated with hydraulic fracturing activities. Their findings further suggested that seismic activity resulted from “stress changes due to the elastic response of the rockmass to hydraulic fracturing,” as well as “pore-pressure changes due to fluid diffusion along a permeable fault zone.”⁷⁴⁰ In contrast to the central United States, where induced seismic activity is primarily caused by massive underground disposal of fracking waste, these findings pointed to the fracking process itself as the trigger. In an interview with the *New York Times*, co-author David Eaton compared fracking to a series of “small underground explosions” that travel into the rock formation and “rapidly change the stress patterns within.” These stress changes can be sufficient to trigger a slip at a critically stressed, previously undetected fault.⁷⁴¹

- November 17, 2016 – An investigation by the *Dallas Morning News* chronicled a pattern of corruption and regulatory failings at the Texas Railroad Commission, the state agency charged with overseeing the oil and gas industry, in its disregard of evidence linking fracking waste disposal to earthquakes in North Texas.⁷⁴²
- November 8, 2016 – On November 6, 2016, a magnitude 5.0 earthquake struck Cushing, Oklahoma near the oil hub where 60 million barrels of crude oil were stored. The quake injured one, damaged more than 40 buildings, closed a school, and triggered evacuations. Oil infrastructure was not damaged.⁷⁴³ (See also entry above for September 14, 2017.)
- October 7, 2016 – The EPA recommended a moratorium on the underground injection of fracking wastewater in certain earthquake-prone parts of Oklahoma after a 5.8 earthquake struck near Pawnee on September 3, 2016.⁷⁴⁴ The strongest in Oklahoma’s history, the Pawnee earthquake was felt by residents in five states and prompted a state of emergency declaration as well as an order from state regulators to shut down 67 wastewater disposal wells in the area.^{745, 746}
- September 22, 2016 – A study using satellite-based radar imagery found that the earth’s surface rose, by 3 millimeters per year, in areas of fracking waste injection. Underground

pore pressures for this area exceeded those known to trigger earthquakes. These findings provide proof that the migration of fracking wastewater into faults increased pressures in ways that triggered a 4.8 magnitude earthquake in east Texas in 2012. The researchers emphasized that pore pressure elevation and propagation from fracking wastewater injection may evolve over periods of months to years before affecting critically stressed faults.⁷⁴⁷

- September 14, 2016 – Researchers from the USGS used a newly deployed seismic monitoring network to document the rupture of a fault plane that set off a magnitude 4.9 earthquake in Milan, Kansas in 2014, immediately following a rapid increase in fracking wastewater injection nearby.⁷⁴⁸
- May 2016 – In a study that has “far-reaching implications for assessment of induced-seismicity hazards,” a Canadian team of researchers determined that hydraulic fracturing itself is linked to earthquake swarms in western Canada, in contrast to the central United States where disposal of fracking waste is the cause of most induced seismicity. Furthermore, lowering the volume of injected fluid may not be sufficient to prevent quakes. In the Western Canada Sedimentary Basin, “it appears that the maximum-observed magnitude of events associated with hydraulic fracturing may exceed the prediction of an often-cited relationship between the volume of injected fluid and the maximum expected magnitude.... Rather, we propose that the size of the available fault surface that is in a critical state of stress may control the maximum magnitude.... Our results indicate that the maximum magnitude of induced events for hydraulic fracturing may not be well correlated with net injected fluid volume.”⁷⁴⁹
- April 29, 2016 – Five small earthquakes in one 24-hour period originated in an area in Lawrence County, Pennsylvania near a fracking operation that was drilling into the deep Utica Shale at the time. Quoted in the *Pittsburg Post-Gazette*, researchers noted that it is very difficult for operators to avoid areas with faults because their locations are very often unknown.⁷⁵⁰
- March 28, 2016 – A summary of the evidence linking drilling and fracking activities to earthquakes appeared in *Scientific American*. Emerging data suggests that pressure changes caused by fracking wastewater injection can migrate for years before encountering a geological fault and altering stresses in ways that allow for slippage. In this way, earthquake risks can spread out over both time and space—traveling for miles

beyond the disposal well and persisting for a decade or more as injected fluids travel underground. In spite of increasing scientific clarity about these mechanisms, regulators have been slow to respond.⁷⁵¹

- February 1, 2016 – An article in the *Texas Journal of Oil, Gas, and Energy Law* exhaustively reviewed the literature on earthquake activity in areas of six states (Arkansas, Colorado, Kansas, Ohio, Oklahoma, and Texas) where fracking takes place or drilling wastes are disposed underground and concluded that courts should impose strict liability for earthquake damage caused either by fracking itself or by the underground injection of fracking fluids. “Earthquakes sometimes occur when subsurface formations are properly fractured. Likewise, the risk of earthquake damage is not substantially mitigated by the exercise of due care when frack fluids are injected into the ground.”⁷⁵²
- January 22, 2016 – An international research team investigated a swarm of earthquakes in California’s Central Valley that occurred in 2005. Using hydrogeological modeling, the researchers concluded that the underground injection of wastewater from oil drilling operations had contributed to seismicity via changes in localized pressures along an active fault.⁷⁵³
- January 12, 2016 – As reported by *CBC News*, a Canadian regulatory agency ordered a drilling and fracking operation in northwestern Alberta to shut down after a magnitude 4.8 earthquake struck nearby. The operator was fracking at the time the earthquake happened.⁷⁵⁴
- November 15, 2015 – A spokesperson for the Oklahoma Corporation Commission, which regulates the oil and gas industry in the state, said that Oklahoma now leads the world in earthquake frequency.⁷⁵⁵
- October 29, 2015 – The Kansas Corporation Commission extended limits on the injection of wastewater from fracking operations after a drop in the frequency of earthquakes that followed an earlier order to limit such injections.⁷⁵⁶ Between 2013 and October 2015,

Kansas recorded more than 200 earthquakes. Before that, the average rate was one earthquake every two years.

- October 23, 2015 – *Bloomberg* explored the national security risks that fracking-induced earthquakes in Oklahoma create for the nation’s largest oil storage hub in Cushing, where aboveground tanks hold more than 60 million barrels of crude oil and serve as a way station for oil from North Dakota’s Bakken Shale as it heads to Gulf Coast refineries. Earthquake swarms have hit within a few miles of Cushing and may be harbingers of larger quakes in the future. “Now that quakes appear to have migrated closer to Cushing, the issue of what to do about them has morphed from a state issue to one of national security.... Not only is Cushing crucial to the financial side of the oil market, it is integral to the way physical crude flows around the country.”⁷⁵⁷
- September 21, 2015 – An international team of geologists investigated possible causes of the Lusi mudflow, which began suddenly in 2006 when mud began erupting from the ground in a volcano-like fashion in an urban area of Java in Indonesia. The ongoing disaster has, as of 2015, displaced 39,700 people and cost nearly \$3 billion in damages and disaster management. Looking at data on the emissions of subsurface gases before and after the eruption began, the team concluded that the likely cause was nearby gas drilling that forced fluid into the clay layer via the open well. “We therefore conclude that the Lusi eruption was not triggered naturally but was instead the consequence of drilling operations.”⁷⁵⁸ In interviews with the *New York Times*, lead author Mark Tinjay said, “We are now 99 percent certain that the drilling hypothesis is valid,” while other experts who were not authors of the paper expressed less certainty.⁷⁵⁹
- July 27, 2015 – During a seven-day period in late July, the state of Oklahoma experienced 40 earthquakes. According to the USGS, three registered above magnitude 4.0, one of which was strong enough to be felt by 1.9 million people, including residents of several surrounding states.⁷⁶⁰ In response, gas and oil operators voluntarily shut down two nearby wastewater injection wells and reduced operations by half at a third well.⁷⁶¹ According to the Oklahoma Geological Survey, the recent quakes are occurring along a fault line that extends north of Oklahoma City and signal greater potential for a larger earthquake.⁷⁶² Ten days before the voluntary shutdowns, the Oklahoma Corporation Commission, which regulates the oil and gas industry, put 211 wastewater disposal wells

under extra review.⁷⁶³ The next month, Oklahoma regulators, acknowledging that previous efforts have been unsuccessful in reducing seismic activity, asked operators of 23 injection wells to decrease the amount of wastewater injected by 38 percent and signaled that more sweeping regulatory actions may follow.⁷⁶⁴

- July 1, 2015 – Two researchers, from the USGS and the Geological Survey of Canada, offered a summary of the history, basic geology, and engineering of fracking fluid injection and induced seismicity. Noting that since 2001 Oklahoma had experienced two earthquakes of very large magnitude (5.0 and 5.3), the authors called for “a detailed understanding of the physical processes involved in inducing large magnitude events and a detailed understanding of the geology and hydrology at the site of the earthquakes.” They also noted that many important parameters are either unknown or not easily constrained, making it “difficult to determine the wells that will induce earthquakes and those that will not.”⁷⁶⁵
- June 30, 2015 – The Oklahoma Supreme Court ruled that homeowners who have sustained injuries or property damage that they believe is due to earthquakes caused by oil and gas operations can sue for damages in state trial courts. The number of earthquakes with magnitude 3.0 or higher has skyrocketed in Oklahoma, with 1,100 predicted to occur in 2015. Earlier this year, scientists at the state’s geological survey reversed prior views and embraced the conclusion that the majority of the recent earthquakes in central and north-central Oklahoma were “very likely triggered” by underground wastewater disposal. Industry lawyers have complained that liability for such damages will be economically unsustainable. A separate class action lawsuit is planned.⁷⁶⁶
- June 19, 2015 – By compiling a database of 187,570 injection wells in the central and eastern United States, University of Colorado Boulder and USGS researchers were able to test for associations between fracking waste disposal and earthquakes. Results showed far more injection wells were potentially related to earthquakes than had previously been realized, and active disposal-only wells were more than 1.5 times more likely than active oil extraction wells to be associated with an earthquake. In addition, high-rate injection wells, receiving more than 300,000 barrels of fluid per month, were much more likely than lower-rate wells to be associated with an earthquake, while other factors, including wellhead injection pressure, appeared unrelated to increased earthquake activity. The

study called for managing injection rates as “a useful tool to minimize the likelihood of induced earthquakes.” The researchers did not address the impact of hydrofracturing activities *per se* as a potential confounding variable.^{767, 768}

- June 18, 2015 – Close examination of several areas in Oklahoma by Stanford University geophysicists revealed that dramatic increases in recent earthquake activity followed 5- to 10-fold increases in deep-well injection of briny “produced water,” the highly salty fluid that rises to the surface from water-bearing oil reserves and requires disposal. The rate of earthquake occurrence, which began to increase in 2009, is now 600 times higher than it was before the onset of widespread fracking in the state. The disposal of this type of waste in Oklahoma mostly occurs via injection into geological formations that appear to be in hydraulic communication with potentially active faults in the crystalline basement. The study proposed that increasing pressure, spreading away from injection wells over time, could eventually trigger slips on critically stressed faults, resulting in earthquake activity. It is likely that, “even if injection from many wells were to stop immediately, seismicity would continue as pressure continues to spread out from past injection.”⁷⁶⁹
- June 12, 2015 – Researchers in France uncovered an unexpected mechanism by which subsurface fluid injections, such as those used in high volume hydrofracturing, can cause earthquakes. They found that injection of pressurized water can cause fault lines to “creep” rather than slip suddenly as occurs during earthquakes. Earthquakes did follow this slow movement but took place in a portion of the fault outside the pressurized zone. This research demonstrated that subsurface injection of fluids under pressure can cause primary gradual slippage of fault planes leading to secondary sudden seismic activity.^{770, 771}
- June 11, 2015 – As reported by the Vancouver news magazine *The Tyee*, seismic events of magnitude greater than 2.0 (but less than 4.0) in the Fox Creek area were reported in Alberta, Canada since the initiation in February of a novel “traffic light system” for responding to measured seismic activity. The system requires varying responses according to the magnitude of the event, ranging from no action up to ceasing operations and informing the Alberta Energy Regulator for events at magnitudes greater than 4.0. Experts noted that the system does not work well when the largest event in the sequence is the first event. Moreover, once a sequence of earthquakes is initiated, the sequence

may continue, sometimes with larger earthquakes, long after potentially causally related drilling or injection activities have ceased.⁷⁷²

- June 1, 2015 – In a data-rich presentation, a team of researchers from St. Louis University, Colorado State University, and USGS concluded that “a fundamental change in the earthquake-triggering process has occurred” in central Oklahoma. Using advanced field monitoring and high-performance software, computer models illustrate active earthquake sequences associated with long fault structures “that might be capable of supporting large earthquakes (M 5 to 6)” and possibly cascades of earthquakes, which could occur near population centers and expensive infrastructure associated with the oil and gas industry, such as a large underground crude-oil storage facility.⁷⁷³
- May 11, 2015 – A series of directives from the Oklahoma Corporation Commission revealed a slowly evolving approach to the regulation of disposal well operations in that state, and the gradual tightening of a “traffic light system” introduced in 2013 to determine whether disposal wells for fracking waste should be permitted, permitted only with special restrictions and requirements, or not permitted, in light of the now-proven connection between the injection of liquid waste and the soaring frequency of earthquakes in Oklahoma. Since 2013, earthquake activity in Oklahoma has continued to increase in rate and intensity.^{774, 775}
- April 23, 2015 – In a first-of-its-kind approach, the USGS is updating its National Seismic Hazard Model to address the rapidly increasing, highly variable, and difficult-to-predict hazards of induced earthquakes.⁷⁷⁶ This initial report identified 17 areas within eight states (Alabama, Arkansas, Colorado, Kansas, New Mexico, Ohio, Oklahoma, and Texas) with increased rates of induced seismicity, including many areas experiencing earthquakes of large magnitude.⁷⁷⁷ Two days before the release of this report, Oklahoma’s state government acknowledged for the first time that wastewater disposal related to oil and gas drilling is “very likely” to blame for the huge surge of earthquakes

in many areas of Oklahoma, the *New York Times* reported.⁷⁷⁸ Several states have developed protocols to shut down existing wells and halt drilling of new disposal wells following an upsurge in earthquake activity.

- April 21, 2015 – Analyzing the unusual increase of seismicity in north Texas since 2008, researchers from Southern Methodist University, the USGS, and University of Texas at Austin concluded that observed earthquake swarms were associated both with extraction (of gas and brine formation waters) and injection (of fracking wastewater), via significant stress changes at earthquake depths. The research team noted that baseline pressure monitoring data, though easy to obtain and routinely collected by industry at well sites, were currently “neither required nor typically available for analysis.” Greater transparency and cooperation in regional seismic monitoring is needed to generate more comprehensive data sets that are necessary for robust earthquake hazard analysis, they asserted.^{779, 780}
- April 21, 2015 – In a statement reporting on an increase in earthquakes in Oklahoma of greater than magnitude 3.0 from less than two per year historically to over two per day in 2015, the Oklahoma Geological Society acknowledged that the primary, suspected source of “triggered seismicity” is the injection and disposal of produced water associated with oil and gas production.⁷⁸¹
- March 30, 2015 – *Bloomberg Business* reported that Oklahoma state seismologists had received pressure from oil industry representatives to downplay the evidence linking fracking wastewater disposal to the soaring frequency of earthquakes in the state.⁷⁸²
- March 6, 2015 – A careful and detailed analysis of historical data coupled with onsite, real-time measurements of seismic activity in central Oklahoma via rapidly deployed seismic sensors revealed that reactivated ancient faults responsible for thousands of earthquakes in Oklahoma are capable of causing larger seismic events. Current hazard maps did not include induced seismicity and therefore underestimate earthquake hazard, the USGS reported. Until new hazard maps become available, providing information about the type, length, and location of these reactivated faults could provide guidance to the oil and gas industry and help inform public policy decisions.⁷⁸³ In addition, noted lead

author Dan McNamara, such information can “aid in adapting building codes to ensure that structures can withstand more damaging earthquakes.”⁷⁸⁴

- February 20, 2015 – Scientists with the USGS reported in *Science* about grappling with an unexpected increase in injection-related seismic activity across the middle of North America. In 2014, the number of measured earthquakes with magnitude of 3 or greater in Oklahoma exceeded that in California, and observations increasingly suggested that the effects of fluid injection were not confined to the target formation but instead were communicated, sometimes to greater depths, along pre-existing faults. Making hazard modeling more difficult, “most of these faults are only detected when they are imaged by well-located induced earthquakes.” Consequently, predicting and controlling such seismic activity may not be possible, leading to a recommendation that injection projects should be sited away from population centers.⁷⁸⁵
- February 5, 2015 – Citing an association between increased water use and fracking-induced seismic activity, a research scientist at the Geological Survey of Canada offered the quantity of water injected underground as his hypothesis for an observed increase in the frequency and magnitude of earthquake activity in areas near fracking wells. Although the Council of Canadian Academies in 2014 called for more monitoring and data collection, there are only ten monitoring stations in British Columbia, overseeing the operations of thousands of fracking wells, reported the *Vancouver Observer*.⁷⁸⁶
- January 29, 2015 – The industry-funded Alberta Energy Regulator confirmed that the location of an earthquake of magnitude 4.4 near Fox Creek, Alberta, was “consistent with being induced by hydraulic fracturing operations,” making it the largest felt earthquake yet believed to be related to fracking. Despite claims from industry that tremors related to deep-level fracking could never reach magnitudes that would allow them to be felt on the surface, Gail Atkinson, who holds the Canada Research Chair in Induced Seismicity Hazards at Western University in Ontario, noted, “With fracking, the magnitudes have been increasing every year.”⁷⁸⁷
- January 6, 2015 – Using a specialized program, Miami University researchers analyzed data from multiple seismic stations and determined that a cluster of 77 earthquakes in Poland Township, Ohio, which occurred over the course of a little more than a week, was related temporally and spatially to active hydraulic fracturing operations. When the fracturing operations were shut down, the rate of earthquake activity declined to only 6 events in the next 12 hours and only a single event over approximately the next two

months. Among this cluster of seismic activity, an earthquake of magnitude 3.0 ranks as one of the largest earthquakes in the United States to be induced by hydraulic fracturing. The mechanism for these earthquakes appears to be induction of slip along a pre-existing fault or fracture zone. Because “no known fault or historical seismicity had been [previously] identified in the area,” regulations prohibiting fracturing within three miles of a known fault would not have been protective.^{788, 789}

- December 18, 2014 – In Canada, an investigation by the British Columbia Oil and Gas Commission found that induced seismicity in the Horn River Basin could be attributed both to wastewater disposal and to hydraulic fracturing operations. The Commission recommended mitigation of induced seismicity from wastewater disposal by “reducing injection rates, limiting the increase in [subsurface] reservoir pressure, and locating distal from faults,” among other mitigation techniques.^{790, 791}
- October 23, 2014 – Researchers from USGS and the Global Seismological Services in Golden, Colorado, linked a 2011 magnitude 5.3 earthquake in Colorado, which damaged the foundations of several homes, to underground disposal of fracking wastewater. The study determined that the earthquake ruptured an 8-10 kilometer-long segment of normal faults—an unexpectedly long length for a magnitude 5.3 earthquake—suggesting that wastewater disposal may have triggered a low stress drop.⁷⁹² Lead author Bill Barnhart, a USGS geophysicist, told *Reuters*, “We saw a big increase in seismicity starting in 2001, including magnitude 5 earthquakes, in many locations in the basin, and that coincided with a surge in gas production and injection of wastewater.”⁷⁹³
- September 23, 2014 – Youngstown State University geologist Ray Beiersdorfer described increased seismic activity in Youngstown, Ohio in an essay that explores how fracking and fracking-related processes are causing “earthquake epidemics” across the United States.⁷⁹⁴

- September 15, 2014 – Researchers at the National Energy Technology Laboratory teamed up with researchers from industry and academia to publish data and analysis from a closely watched project that involved field monitoring of the induced fracturing of six horizontal Marcellus Shale gas wells in Greene County, Pennsylvania. Touted in earlier media reports as demonstrating that, during short-term follow-up, fracking chemicals injected into these six wells did not spread to overlying aquifers⁷⁹⁵, the study’s most notable finding is striking documentation of fractures from three of the six wells extending vertically to reach above an overlying rock layer previously thought to create an impenetrable “frac barrier” (that is, an upper barrier to fracture growth). In one case, a fracture extended vertically 1,900 feet, a surprisingly far distance. No pre-existing fault had been detected at this location, suggesting that small “pre-existing fractures or small-offset (sub-seismic) faults may have focused the energy of hydraulic fractures on certain areas....” Perhaps because of the extremely small sample size and a design focused primarily on monitoring for potential gas and fluid migration, the study’s analysis includes no discussion of the seismic relevance of extremely long, vertical induced fractures.⁷⁹⁶
- September 15, 2014 – Scientists from USGS ascribed causality to wastewater injection wells from coal-bed methane production for increases in seismic activity in New Mexico and Colorado and, in particular, for an earthquake that measured magnitude 5.3 in Colorado in 2011—the second largest earthquake to date for which there is clear evidence that the earthquake sequence was induced by fluid injection.⁷⁹⁷
- September 6, 2014 – The Ohio Department of Natural Resources suspended operations at two deep-injection wells for fracking wastewater near Warren in northeastern Ohio after discovering evidence that the operation possibly caused a magnitude 2.1 earthquake. The injection well operator, American Water Management Services, had recently received permission to increase pressures at the site of the wells. In 2012, Governor John Kasich had halted disposal of fracking wastewater surrounding a well site in the same region after a series of earthquakes were tied to a deep-injection well. The company that ran that well has disputed the link. The state placed seismic-monitoring devices in the Warren area under protocols adopted after the series of earthquakes in nearby Youngstown.⁷⁹⁸

- September 1, 2014 – Explaining the need for increased seismic monitoring, Andrew Beaton, Director of the Alberta Geological Survey, stated that over a long period of time, stresses increase in and around an injection wellbore. Seismic movement can be caused if the rate of injection is too fast or if there is a geological feature, such as a fault or fracture in nearby areas. Although Albertans in rural areas have been reporting for years that they can feel tremors under their feet near oil and gas activity, especially around areas of fracking, the Alberta Energy Regulator noted that deep well injections have been shown to create more of an earthquake hazard than hydraulic fracturing. Alberta experienced 819 earthquakes between 1918 and 2009. In comparison, Saskatchewan recorded 13 in the same time period and British Columbia recorded more than 1,200 earthquakes in 2007 alone. There are currently 24 seismic monitors in Alberta, which are tied into other networks, such as those belonging to Environment Canada, University of Calgary, and University of Alberta.⁷⁹⁹
- August 26, 2014 – In a first-of-its-kind lawsuit, a resident of Prague, Oklahoma, sued two energy companies after rocks fell from her chimney and injured her leg during an earthquake of greater than magnitude 5. The lawsuit claims that underground injection of fracking wastewater conducted by New Dominion LLC and Spess Oil Company has caused shifts in fault lines that have resulted in earthquakes.⁸⁰⁰
- July 31, 2014 – William Ellsworth, a research geophysicist at the USGS Earthquake Science Center, reported that USGS is developing a hazard model that takes induced earthquakes into account. In addition, residents of Oklahoma, where a sharp spike in earthquake activity has been noted over the past decade, are showing an increased interest in obtaining earthquake insurance.⁸⁰¹
- July 3, 2014 – Using data from the Oklahoma Corporation Commission, a team of researchers led by Cornell University geophysicist Katie Keranen found that a steep rise in earthquakes in Oklahoma can be explained by fluid migration from wastewater disposal wells. Moreover, injected fluids in high volume wells triggered earthquakes over 30 kilometers (over 18 miles) away. All of the wells analyzed were operated in compliance with existing regulations. Similar mechanisms may function in other states with high volumes of underground injection of wastewater from unconventional oil and gas production.⁸⁰² Reporting on the study and the increase in earthquakes across the United States and the link to fracking and wastewater disposal, the *Associated Press*

noted that some states, including Ohio, Oklahoma, and California, have introduced new rules compelling drillers to measure the volumes and pressures of their injection wells as well as to monitor seismicity during fracking operations.⁸⁰³

- July 1, 2014 – Seismologists linked the emergence of a giant sinkhole that formed in August 2012 near Bayou Corne in southeast Louisiana to tremors (earthquakes) caused by high-pressure pulses of either natural gas or water charged with natural gas. The surges of natural gas that caused the explosive tremors (earthquakes) may have weakened an adjacent salt cavern and caused its collapse. Alternatively, part of the salt cavern may have collapsed, causing a nearby gas pocket to give off surges of gas, later followed by the complete collapse of the salt cavern. These findings help illuminate the role of pressurized fluids in triggering seismic events.⁸⁰⁴
- June 24, 2014 – Following two earthquakes within a one-month period, the Colorado Oil and Gas Conservation Commission directed High Sierra Water Services to stop disposing wastewater into one of its Weld County injection wells. Monitoring by a team of seismologists from the University of Colorado had picked up evidence of continuing low-level seismic activity near the injection site, including a magnitude 2.6 event less than a month following a magnitude 3.4 earthquake that shook the Greeley area on May 31, 2014.⁸⁰⁵
- May 2, 2014 – The USGS and Oklahoma Geological Survey (OGS) jointly issued an official earthquake warning for Oklahoma, pointing out that the number of earthquakes in the state has risen 50 percent since just October—when the two agencies had issued a prior warning. The advisory stated that this dramatic increase in the frequency of small earthquakes “significantly increases the chance for a damaging quake in central Oklahoma.” Injection wells used for the disposal of liquid fracking waste have been implicated as the presumptive cause of the earthquake swarm. According to the OGS, about 80 percent of the state of Oklahoma is closer than ten miles from an injection well.⁸⁰⁶ Since the joint earthquake advisory was released in May, the number of earthquakes in Oklahoma has continued to rise. During the first four months of 2014, Oklahoma had experienced 109 earthquakes of magnitude 3 or higher on the Richter

scale. By mid-June, the number of earthquakes had topped 200, exceeding the frequency of earthquakes in California.⁸⁰⁷

- May 2, 2014 – At the annual meeting of the Seismological Society of America, leading geologists warned that the risks and impacts of earthquakes from fracking and injection wells are even more significant than previously thought, pointing out that such earthquakes could occur tens of miles away from wells themselves, including quakes greater than magnitude 5.0. Justin Rubinstein, a research geophysicist at the USGS said, “This demonstrates there is a significant hazard. We need to address ongoing seismicity.”⁸⁰⁸ Seismologist Gail Atkinson reported, “We don’t know how to evaluate the likelihood that a [fracking or wastewater] operation will be a seismic source in advance.”⁸⁰⁹
- April 11, 2014 – State geologists reported a link between fracking and a spate of earthquakes in Ohio, prompting the Ohio Department of Natural Resources to place a moratorium on drilling in certain areas and to require greater seismic monitoring.⁸¹⁰
- April 3, 2014 – Researchers linked earthquakes in Mexico to fracking in the Eagle Ford Shale, which extends beneath both southern Texas and northern Mexico. They also noted a statistical correlation between seismic activity and fracking, particularly in the border state of Nuevo Leon, which registered at least 31 quakes between magnitude 3.1 and 4.3.⁸¹¹
- April 2014 – Researchers from the University of Alberta and the Alberta Geological Survey published a study in the *Journal of Geophysical Research* that found wastewater injection in Alberta is highly correlated with spikes of seismic activity between October 2006 and March 2012.⁸¹² On November 13, 2014, *CBC News* reported on a more recent increase in earthquakes, which may also be linked to injection wells.⁸¹³

- March 7, 2014 – USGS researchers published a study confirming that Oklahoma’s damaging magnitude 5.7 earthquake in 2011 was caused by fracking wastewater injection.⁸¹⁴ One of the authors of the study, seismologist Elizabeth Cochran, noted, “Even if wastewater injection only directly affects a low-hazard fault, those smaller events could trigger an event on a larger fault nearby.”⁸¹⁵
- January 30, 2014 – A USGS research team linked the rise in earthquakes in Colorado to fracking wastewater injection wells and announced that a study will be published in six to nine months.⁸¹⁶
- December 12, 2013 – The *New York Times* detailed the growing link between fracking wastewater injection wells and earthquakes, as well as between fracking itself and earthquakes, with a focus on Oklahoma and a recent magnitude 4.5 earthquake there. As the *New York Times* noted, “Oklahoma has never been known as earthquake country, with a yearly average of about 50 tremors, almost all of them minor. But in the past three years, the state has had thousands of quakes. This year has been the most active, with more than 2,600 so far, including 87 last week.... State officials say they are concerned, and residents accustomed to tornadoes and hail are now talking about buying earthquake insurance.”⁸¹⁷
- November 19, 2013 – *Reuters* reported that a series of Oklahoma earthquakes in September of 2013 damaged several homes, and that more scientists in a number of states are concerned about earthquakes related to oil and gas development. Seismologist Austin Holland with the University of Oklahoma said, “This is a dramatic new rate of seismicity.”⁸¹⁸

faults in ways that make them vulnerable to slipping. The research shows that distant natural earthquakes triggered swarms of smaller earthquakes on critically stressed faults. The researchers wrote, “The fluids [in wastewater injection wells] are driving the faults to their tipping point.... Areas with suspected anthropogenic earthquakes are more susceptible to earthquake-triggering from natural transient stresses generated by the seismic waves of large remote earthquakes.”⁸²¹

- April 2013 – A group of British researchers stated that hydraulic fracturing itself was the likely cause of at least three earthquakes powerful enough to be felt by human beings at the surface. The researchers proposed that increases in the fluid pressure in fault zones were the causal mechanism for these three known instances of “felt seismicity” in the United States, Canada, and the United Kingdom. The largest of these earthquakes was a magnitude 3.8 in the Horn River Basin, Canada.⁸²²
- March 26, 2013 – Scientists from the University of Oklahoma, Columbia University and USGS linked a 2011 swarm of earthquakes in Oklahoma to fracking waste disposal in that state.⁸²³ This included a magnitude 5.7 earthquake—possibly the largest ever triggered by wastewater injection—that injured two people, destroyed 14 homes, and was felt across 17 states.⁸²⁴ The research team concluded in a paper in the journal *Geology* that their data called into question the previously predicted maximum size of injection-induced earthquakes.^{825, 826}
- December 14, 2012 – At a 2012 American Geophysical Union meeting, scientists presented data and concluded that some U.S. states, including Oklahoma, Texas and Colorado, have experienced a significant rise in seismic activity coinciding with a boom in gas drilling, fracking and wastewater disposal. Scientists further found that Oklahoma has seen a significant increase in earthquakes linked to wastewater injection, that a 5.3 earthquake in New Mexico was linked to wastewater injection, and that earthquakes were increasingly common within two miles of injection wells in the Barnett Shale region of Texas. Art McGarr, a researcher at the USGS Earthquake Science Center, concluded that,

“The future probably holds a lot more in induced earthquakes as the gas boom expands.”⁸²⁷

- November 30, 2012, January 11, 2012, December 22, 2009 – In three different sets of comments on proposed fracking guidelines and regulations, citing scientific reports linking oil and gas infrastructure to seismic activity, the New York City Department of Environmental Protection (NYC DEP) raised serious concerns about the impacts of potential seismic activity from fracking-related activities on New York City’s water supply infrastructure.^{828, 829, 830} The NYC DEP has consistently raised concerns that seismic activity surrounding New York City’s aquifers and watershed infrastructure could threaten the city’s drinking water supply by triggering microseismic events and small induced earthquakes that, in turn, could threaten the integrity of the aging, 100-mile-long aqueducts that carry drinking water from the Catskill Mountains into the New York City metropolitan area. The agency expressed specific concerns about the ability of hydraulic fracturing fluids to migrate underground and to intercept and reactivate faults miles away.
- September 6, 2012 – The British Columbia Oil and Gas Commission determined that fracking itself causes earthquakes, pointing to the results of a probe into 38 seismic events near fracking operations in the Horn River Basin. The report noted that no quakes had been recorded in the area prior to April 2009, before fracking began. The report recommended that the link between fracking and seismic activity be further examined.⁸³¹
- March 29, 2012 – The USGS found that between 2001 and 2011, there was a six-fold increase in earthquakes greater than magnitude 3.0 in the middle of the United States that “are almost certainly manmade.” The agency further reported that the increase appears to be linked to oil and gas production and deep injection of drilling wastewater.^{832, 833}

Abandoned and active wells as pathways for gas and fluid migration

Most fracking operations take place in oil and gas fields with a long history of conventional drilling and therefore with many abandoned wells. These can serve as potential pathways for contaminants to migrate vertically. Of the estimated 2.6 million oil and gas wells across the United States that are no longer in production, the location and status of the vast majority are not recorded in state databases, and most remain unplugged. Whether plugged or unplugged, abandoned wells are a significant source of methane leakage into the atmosphere and, based on findings from New York and Pennsylvania, may exceed cumulative total leakage from oil and gas wells currently in production. No state or federal agency routinely monitors methane leakage from abandoned wells. Abandoned wells also serve as underground pathways for fluid migration, heightening risks of groundwater contamination. Fluid can migrate upward through vertical channels when fractures from new drilling and fracking operations intersect with old wells. The most probable pathway of contaminant transport takes place outside the well casing. Industry experts, consultants, and government agencies including the U.S. Environmental Protection Agency (EPA), the U.S. Government Accountability Office (GAO), Texas Department of Agriculture, New York State Department of Environmental Conservation (NYS DEC), Pennsylvania Department of Environmental Protection (PA DEP), Illinois Environmental Protection Agency, and the British Columbia Oil and Gas Commission have all warned about problems with abandoned wells due to the potential for pressurized fluids and gases to migrate through inactive and, in some cases, active wells.

- March 11, 2019 – There are roughly 200,000 abandoned oil and gas wells in Pennsylvania left over from more than a century of drilling. Most are not mapped. Alabama-based Diversified Gas & Oil, which now owns about 23,000 gas wells in the state, reached an agreement with the PA DEP to plug 1,400 abandoned wells over the next 15 years—or bring them back into production. The agreement requires the company to submit a \$7 million performance bond to cover the costs of plugging. In 2018, the company plugged 41 wells across its entire operating area.⁸³⁷
- March 5, 2019 – There are 30,000 abandoned oil wells in California, with 1,850 in Los Angeles County. The state is currently not required to report to the public on toxic air emissions from these wells before, during, or after they are plugged, even when idle wells are located within densely populated residential communities. The process of capping wells can itself release harmful gases. Legislation has been proposed to remediate this oversight.⁸³⁸
- February 21, 2019 – While preparing to mine over a natural gas storage field in Greene County, Pennsylvania, a coal company discovered dozens of undisclosed abandoned gas

wells at the site, according to a report by the *Pittsburgh Post-Gazette*. “Pennsylvania’s history of fossil fuel extraction, combined with modern operations harvesting coal, oil and gas at different depths, makes it a particularly thorny place to work underground.”⁸³⁹

- January 25, 2019 – Colorado Governor John Hickenlooper signed an executive order to force the “plugging, remediation and reclamation of all medium- and high-priority orphaned wells and orphaned sites.” There are roughly 55,000 oil and gas wells in Colorado. At least 260 are orphaned, which means that the well’s owner cannot be identified, usually because of bankruptcy. Inactive wells that are orphaned become the responsibility of the state.⁸⁴⁰
- December 21, 2018 – Most fracking operations take place in oil and gas fields with a long history of conventional drilling and therefore with many abandoned wells. The possibility of hydraulic fractures intercepting these old wells and opening a pathway for rapid vertical transport for fluids to the surface or to groundwater aquifers depends on multiple variables. A University of Goettingen-led team used modeling to explore the relevant factors that predict long-term flow and transport of fracking fluids into groundwater aquifers through a leaky, abandoned well. The results showed that wellbore integrity of the abandoned well and its distance from the fracking operation are the two most influential parameters determining the vertical transport of fracking fluid through an abandoned well. The most probable pathway of contaminant transport takes place outside the well casing. Hydraulic fracking fluid tends to spread laterally when sediment layers are permeable, decreasing upward movement of fluid and decreasing contamination distribution in the aquifer. When freshwater aquifers are shallow, the short-term probability of contamination is negligible even in the presence of a leaky, abandoned well. “Model results show that hydraulic fracturing fluid reaches the aquifer three years after production.”⁸⁴¹
- December 15, 2018 – A University of Vermont-led team explored the ability of various predictive models to forecast fluid migration from and through abandoned wells in Alberta, Canada. Although all the models “performed better than random guessing,” none of them perfectly predicted which wells would leak in part because of incomplete data. In Alberta, wells that do not leak at the time they are drilled are not retested until they are abandoned. Continuous monitoring of wells in a small area would allow the models to be retrained with more accurate information. Consistent with previous findings, the models

⁸⁴¹ Taherdangkoo, R., Tatomir, A., Anighoro, T., & Sauter, M. (2019). Modeling fate and transport of hydraulic fracturing fluid in the presence of abandoned wells. *Journal of Contaminant Hydrology*, 221, 58-68. Advance online publication. doi: 10.1016/j.jconhyd.2018.12.003

did show that the most important features in predicting whether an abandoned well will leak is the deviation of the well from vertical and the year the well was constructed.⁸⁴²

- November 20, 2018 – An investigation by WPXI, an NBC-affiliated television station in Pittsburgh, reported that Pennsylvania lacks funds to locate, plug, and remediate all potentially dangerous abandoned wells in the state. “Overall the problems could cost the state close to \$4 billion, so it is responding to the most critical cases first.”⁸⁴³
- November 20, 2018 – There are an estimated 12,000 abandoned wells in West Virginia, of which 4,000 are orphaned and have no owners, according to a story in the *Charleston Gazette-Mail* that reported how gas companies are saving money by leaving depleted wells behind instead of plugging them.⁸⁴⁴
- September 5, 2018 – An investigation of abandoned wells on Native American lands in the San Juan Basin found that the Bureau of Land Management (BLM), responsible for monitoring oil and gas wells on most tribal lands, has routinely failed to require operators to file paperwork on abandoned wells, lacks a clear strategy for identifying them, and does not prioritize cleaning up or remediating them.⁸⁴⁵
- May 16, 2018 – The GAO reported to Congress that BLM needs to improve its oversight of abandoned oil and gas wells. Companies are supposed to provide bonds up front to cover the costs of plugging abandoned wells and reclaiming the sites, but if they don’t, or if the costs exceed expectations, BLM can be liable and taxpayers can shoulder the clean-up costs. “Reclamation costs and potential liabilities likely increased since 2010, but we couldn’t determine how much because BLM does not systematically track the data.” The GAO recommended that, among other things, the director of BLM should systematically track the actual costs that the agency incurs when reclaiming orphaned wells, the number of orphaned and abandoned wells over time, and the information needed to determine the agency’s potential liabilities. The BLM concurred with the GAO’s recommendations. There are roughly 94,000 oil and gas wells on federal lands overseen by BLM.⁸⁴⁶
- Dec 26, 2017 – In 1965, a blowout at a gas well in northeastern Netherlands caused the formation of quicksand, which swallowed up an entire drill rig. Eventually, the area was

turned into a park. More than 50 years later, a team of researchers discovered that the site is still leaking methane. They found in the groundwater high levels of methane with an isotopic composition that matched that of the gas reservoir. An analysis of groundwater flow conditions showed that this methane is not a remnant of the blowout but the result of ongoing leakage. “Combined, the data reveal the long-term impact that underground gas well blowouts may have on groundwater chemistry, as well as the important role of anaerobic oxidation in controlling the fate of dissolved methane.”^{847, 848}

- June 28, 2017 – *The Tyee* made public the results of an unreleased 2016 report by the Alberta Energy Regulator (AER) showing that 36 of 335 abandoned oil and gas wells that are located close to occupied buildings in urban areas of Alberta are leaking methane. Six abandoned wells were leaking at levels (10,000 ppm) that pose explosion risks and are considered life-threatening. (Natural background level is about 1.9 ppm.) Based on these findings, the report also estimated that 17,000 of 170,000 abandoned wells in rural Alberta were likely also leaking. The author of the unreleased report said in an interview with *The Tyee* that AER, a corporation that functions in part as a regulatory agency, does not have the capacity to evaluate the potential threat to public health and safety. “The expertise to assess the health risk of abandoned wells really doesn’t exist in house.”^{849, 850}
- March 27, 2017 – In an experimental study, Canadian researchers injected methane gas into a shallow sand aquifer over a 72-day period and monitored methane migration for eight months. After 72 days, they found that half of the methane had vented into the atmosphere and half remained in the groundwater, traveling laterally a greater distance than expected and degrading at a rate less than expected. “Our findings demonstrate that even small-volume releases of methane gas can cause extensive and persistent free phase and solute plumes.”^{851, 852}
- December 21, 2016 – *The Texas Tribune* investigated abandoned oil wells in Texas where the Texas Railroad Commission, which is charged with regulating the oil and gas industry, has tracked and mapped 6,628 unplugged, orphaned wells. The commission is struggling with a ballooning inventory of inactive, leaking wells and decreasing clean-up funds to deal with them. The most recent oil boom, involving horizontal drilling with fracking, added to the problem as drillers cut corners in the rush to bring oil to market.

“Just drill the well as fast as possible, because they were under such pressure to get cash flow going,” according to a geoscientist interviewed for the story who had recently retired as a groundwater advisor for the Railroad Commission.⁸⁵³

- November 14, 2016 – Methane emissions from abandoned wells vary widely, with a few high emitters responsible for a disproportionately large share of the problem. Using new field measurement and data mining techniques, a Stanford University-led team investigated gas leaks at 88 inactive wells in Pennsylvania in an attempt to identify the characteristics of these “super-emitters.” Their results showed that unplugged gas wells and wells located in coal areas had the highest methane flow rates. Well plugging does not always reduce methane emission, especially when the wells are vented. In many areas with extensive coal layers, decommissioning requirements for wells included mandatory venting. Using comprehensive databases, the team also estimated the number of abandoned wells in Pennsylvania to be between 470,000 and 750,000, considerably more than previous estimates of 300,000 to 500,000. The research team calculated that, all together, Pennsylvania’s abandoned wells contribute 5-8 percent of the state’s annual greenhouse gas emissions.^{854, 855}
- June 20, 2016 – Pennsylvania’s attorney general began reviewing regulations requiring drillers to document abandoned oil and gas wells within 1,000 feet of a new fracking site. According to a *Bloomberg* investigation, “This puts Pennsylvania among states such as California, Texas, Ohio, Wyoming and Colorado confronting the environmentally catastrophic legacy of booms as fracking and home development expand over former drilling sites. As the number of fracked wells increases, so does the chance they might interact with lost wells.” As noted by *Bloomberg*, state databases document only about 10 percent of the nation’s 2.6 million abandoned oil and gas wells; the whereabouts of the vast majority are unknown. Current efforts in Pennsylvania to increase documentation on the location and status of inactive wells rely on “citizen scientists” equipped with GPS and methane sniffers, as well as home and farm-owners living on top of abandoned wells. Over a period of three decades, PA DEP has located and plugged only about 3,000 abandoned wells.⁸⁵⁶
- May 30, 2016 – New developments of houses, schools, and shopping centers are being built over abandoned oil and gas wells, according to a report by Wyoming Public Media. In most states there is no requirement for homeowners to be notified about abandoned

wells on their properties, and these wells are not systematically monitored for leaks, nor are their locations well mapped. A builder who worked in the oil and gas industry for decades and suffered cardiac arrest when methane from an abandoned well he was inadvertently working atop exploded, said that there were “no signs” that a well was there.⁸⁵⁷

- January 26, 2016 – Researchers tested soil methane levels at 102 United Kingdom decommissioned oil and gas wells between 8 and 79 years old. Thirty percent of the wells had methane at the soil surface that was significantly higher than their control samples in nearby fields. Thirty-nine percent of well sites had significantly lower surface soil methane than their respective controls. Researchers suggested several explanations for the latter results, including replaced soils.⁸⁵⁸
- October 20, 2015 – Abandoned oil and gas wells near fracking sites can be conduits for methane escape that is not currently being measured, according to University of Vermont researchers. Fractures in the surrounding rock may connect to existing unused oil and gas wells in the area during fracking processes, thus providing a pathway for methane to migrate to the surface. The study used a mathematical model based on the large part of southern New York State underlain by the Marcellus Shale, incorporating “the depth of a new fracturing well, the vertical growth of induced fractures, and the depths and locations of existing nearby wells.” The researchers concluded the probability that new fracking-induced fractures would connect to a pre-existing well to be .03 percent to 3 percent. Density of nearby abandoned wells was the largest factor, and researchers pointed out the continuing problem of undocumented abandoned wells.⁸⁵⁹ As noted in an accompanying press release, probabilities are likely much higher: “Industry-sponsored information made public since the paper was published vastly increased assumptions about the area impacted by a set of six to eight fracking wells known as a well pad – to two square miles – increasing the probabilities cited in the paper by a factor of 10 or more.”⁸⁶⁰
- July 9, 2015 – As part of an extensive, peer-reviewed assessment of fracking in California, the California Council on Science and Technology identified leakage through failed, inactive wells as a known mechanism for fracking-related water contamination in other states, including Texas and Ohio, and said that it is not known whether abandoned wells in California likewise function as conduits for groundwater contamination and gas leakage. In California, there are more inactive than active wells. Of the state’s nearly one-quarter million oil and gas wells, more than half (116,000) have been plugged and abandoned, while another 1,800 inactive wells are “buried” with only an approximate

location known. The locations of another 338 old wells are entirely unknown. California also has 110 orphaned wells, that is, abandoned wells with no owners. Most of California's abandoned wells (53 percent) are located in Kern County.⁸⁶¹

- May 11, 2015 – *CBC News* reported that falling gas and oil prices have prompted many smaller companies to abandon their operations in Alberta, Canada, leaving the provincial government to close down and dismantle their wells. In the past year alone, the number of orphaned wells in Alberta increased from 162 to 702. At the current rate of work, deconstructing the inventory of wells abandoned just in the past year alone will be a 20-year task.⁸⁶²
- April 27, 2015 – In a peer-reviewed study, researchers with the U.S. Fish and Wildlife Service documented 5,002 wells located on National Wildlife Refuge System units, in addition to 1,339 miles of pipeline. Almost half of the wells were inactive, while one-third were active and the remainder either plugged and abandoned or with status unknown. Highlighting the impacts of leaks, spills, and routine operation and maintenance on wildlife conservation efforts, the authors called for regular on-site ecological assessments, improved efforts to plug inactive wells and restore inactive well sites, and a “consolidated and robust regulatory framework” to protect the public's interests.⁸⁶³
- March 24, 2015 – Analyzing data from 42 abandoned oil and gas wells in western Pennsylvania, a Princeton and Stanford team documented a wide range of leakage potentials. As a group, gas wells have higher permeability than oil wells. Among gas wells, methane flow rates are positively correlated with permeability. Subterranean temperatures and temperatures, along with well depth, are all variables that can influence leakage potentials of abandoned wells. The leakage potential of wells drilled prior to 1960 is moderate to high, and plugged wells, as well as unplugged wells, can leak. The authors note that cement plugs are imperfect barriers that can develop defects that allow fluids to flow through gaps between the plug and surrounding hole, through pores or fissures within the plug itself, or directly through cracks in the well casing.⁸⁶⁴
- December 8, 2014 – A Princeton University team found that abandoned oil and gas wells in Pennsylvania, left over from prior decades of conventional drilling, leak significantly more methane than previously thought. Between 300,000 and 500,000 abandoned oil and gas wells are located in Pennsylvania, and many go unchecked and unmonitored for

leaks. Nearly three-quarters are unplugged. Based on direct measurements of methane flow from 19 such wells, most of which were a half century old or older, the researchers estimated that the methane leaks from abandoned wells alone could account for between 4 and 7 percent of human-caused methane emissions in the state. Based on these measurements of positive methane flow from decades-old wells, the authors concluded that cumulative emissions from these abandoned wells “may be significantly larger than the cumulative leakage associated with oil and gas production, which has a shorter lifetime of operation.” Further, methane flow rates from plugged wells measured in this study were not consistently lower than unplugged wells and indeed were sometimes higher, even though wells are plugged for the precise purpose of limiting the escape of gases. The authors noted that an estimated three million abandoned oil and gas wells are scattered across the United States and likely represent “the second largest potential contribution to total US methane emissions above US Environmental Protection Agency estimates.” In the United States, no regulatory requirements for monitoring methane leaks from abandoned wells exist.^{865, 866}

- December 1, 2013 – An analysis of reports from the NYS DEC found that three-quarters of the state’s abandoned oil and gas wells were never plugged. New York State has approximately 48,000 such wells; many of their locations remain unknown.⁸⁶⁷
- Aug. 4, 2011 – A report from the EPA to Congress in 1987—and discovered by the *New York Times*—concluded that abandoned natural gas wells may have served as a pathway for hydraulic fracturing fluids to migrate underground from a shale gas well to a water well in West Virginia. In noting that the water well was polluted due to hydraulic fracturing and that such contamination was “illustrative” of contamination from oil and natural gas drilling, the report suggested that additional cases of groundwater contamination from hydraulic fracturing may exist.⁸⁶⁸
- April 4, 2011 – *ProPublica* reported that abandoned wells have caused problems across the nation including contamination of drinking water in Colorado, Kentucky, Michigan, New York, Texas, and other states. *ProPublica* also found that a draft report from the Pennsylvania DEP described a 2008 incident in Pennsylvania in which a person died in an explosion triggered by lighting a candle in a bathroom after natural gas had seeped into a septic system from an abandoned well. The same draft report documented at least two dozen additional cases in which gas leaked from old wells, and three in which gas

from new wells migrated into old wells, seeping into water supplies and requiring the evacuation of homes.⁸⁶⁹

- May 20, 2010 – The British Columbia Oil and Gas Commission issued a safety advisory after hydraulic fracturing caused a large “kick,” or unintentional entry of fluid or gas, into a nearby gas well. The commission reported that it knew of 18 incidents in British Columbia and one in Western Alberta in which hydraulic fractures had entered nearby gas wells. “Large kicks resulted in volumes up to 80 cubic meters [about 100 cubic yards] of fluids produced to surface. Invading fluids have included water, carbon dioxide, nitrogen, sand, drilling mud, other stimulation fluids and small amounts of gas.” These cases occurred in horizontal wells with a distance between wellbores of up to 2,300 feet. The Commission wrote, “It is recommended that operators cooperate through notifications and monitoring of all drilling and completion operations where fracturing takes place within 1000m [3,280 feet] of well bores existing or currently being drilled.” Such communication between active wells raises the potential that similar communication can occur between active wells and abandoned wells.⁸⁷⁰
- 2010 – The NYS DEC cautioned that “abandoned wells can leak oil, gas and/or brine; underground leaks may go undiscovered for years. These fluids can contaminate ground and surface water, kill vegetation, and cause public safety and health problems.” As the agency reported, “DEC has at least partial records on 40,000 wells, but estimates that over 75,000 oil and gas wells have been drilled in the State since the 1820s. Most of the wells date from before New York established a regulatory program. Many of these old wells were never properly plugged or were plugged using older techniques that were less reliable and long-lasting than modern methods.”⁸⁷¹ The agency published similar comments in 2008 and 2009.
- January 2009 – In a presentation before the Society of Petroleum Engineers, industry consultant Michael C. Vincent reported on evidence that fractures from hydraulically fractured wells can communicate with nearby oil and gas wells. In spite of numerous examples of fractures intersecting with adjacent wellbores, the industry is reluctant to publish reports documenting these cases because “such information could unnecessarily alarm regulators or adjacent leaseholders.” Vincent added, “Although computing tools have improved, as an industry we remain incapable of fully describing the complexity of the fracture, reservoir, and fluid flow regimes.” These findings raise the possibility that there could be similar communications between existing fracked wells that are fractured and abandoned wells and that operators cannot accurately predict how these will interact.⁸⁷²

- 2005 – M.K. Fisher, Vice President of Business Management at Pinnacle, a service of Halliburton that specializes in hydraulic fracturing, reported in an article published by the Society of Petroleum Engineers that a single fracture produced during a fracking operation in the Texas Barnett Shale had unexpectedly spread 2,500 feet laterally in two directions. He also described fractures in the Barnett Shale as “extremely complex.”⁸⁷³ These findings raise the possibility that well communication over very large distances could occur due to fractures that spread “unexpectedly.”
- October 1999 – The U.S. Department of Energy reported that there were approximately 2.5 million abandoned oil and gas wells in the U.S.⁸⁷⁴
- Early 1990s – An underground waste disposal well in McKean County, Pennsylvania, contaminated groundwater when the wastewater traveled up a nearby abandoned, unmapped, and unplugged oil well. Owners of private water wells that were contaminated by the incident eventually had to be connected to a public water system.⁸⁷⁵
- July 1989 – In the past, the investigative agency for Congress, the U.S. General Accounting Office (now the Government Accountability Office—GAO) studied oil and natural gas underground injection disposal wells and found serious cases of contamination. The agency reported that, in several cases, wastewater from oil and natural gas operations had migrated up into abandoned oil and natural gas wells, contaminating underground water supplies. The GAO found that “if these abandoned wells are not properly plugged—that is, sealed off—and have cracked casings, they can serve as pathways for injected brines [waste fluids from natural gas and oil drilling] to enter drinking water.... Because groundwater moves very slowly, any contaminants that enter it will remain concentrated for long periods of time, and cleanup, if it is technically feasible, can be prohibitively costly.”⁸⁷⁶
- December 1987 – The EPA submitted a report to Congress on oil and natural gas wastes in which the agency cautioned that abandoned wells must be plugged with cement in order to avoid “degradation” of ground and surface waters as a result of pressurized brine or injected waste from wastewater disposal wells migrating into to aquifers, rivers, or

streams.⁸⁷⁷ While the EPA did not address the potential for contamination through abandoned wells as a result of hydraulic fracturing, both hydraulic fracturing and underground injection disposal wells require underground injection of fluid under pressure, raising the potential that there is a similar risk of groundwater contamination when hydraulic fracturing occurs near abandoned wells.

- 1985 – In an investigation of 4,658 complaints due to oil and natural gas production, the Texas Department of Agriculture found that “when a water well is experiencing an oilfield pollution problem (typically, high chlorides), the pollution source is often difficult to track down. The source could be a leak in the casing of a disposal well, leakage behind the casing due to poor cement bond, old saltwater evaporation pits, or, most often, transport of contaminants through an *improperly plugged abandoned well*” (emphasis in original). The agency found more than a dozen confirmed or suspected cases in which pollutants had migrated up abandoned wells and contaminated groundwater. In one case, drilling wastewater migrated up an abandoned well a half mile away from where the wastewater was injected underground for disposal.⁸⁷⁸
- November 1978 – In a report later cited by the EPA in its 1987 report to Congress (cited above), the state of Illinois Environmental Protection Agency found that oil and natural gas wastes injected underground could migrate through abandoned oil and natural gas wells and contaminate groundwater. The agency wrote, “In old production areas, abandoned wells may pose a serious threat to ground water quality. Unplugged or improperly plugged wells provide possible vertical communication between saline and fresh water aquifers.”⁸⁷⁹

Flood risks

Fracking exacerbates flood risks in two ways. First, massive land clearing and forest fragmentation that necessarily accompany well site preparation increase erosion, run-off, and risks for catastrophic flooding. The construction of access roads, easements for pipelines, and build-out of other related infrastructure further contribute to the problem. Compared to an acre of forest or meadow, an acre of land subject to fracking construction activity releases 1,000-2,000 times more sediment during rainstorms. In addition, in some cases, operators choose to site well pads on flood-prone areas in order to have easy access to water for fracking, to abide by setback requirements intended to keep well pads away from inhabited buildings, or to avoid productive agricultural areas.

Second, the vulnerability of fracking sites to flooding increases the known dangers of unconventional gas extraction, heightening the risks of contamination of soils and water supplies, the overflow or breaching of containment ponds, and the escape of chemicals and hazardous materials. During Hurricane Harvey flooding in Texas in 2017, Eagle Ford operators reported 31 spills at oil and gas wells, storage tanks, and pipelines. Rising sea levels, more powerful hurricanes, and increased storm surges in coastal areas, a consequence of climate change, are expected to represent an increasing threat to oil and gas infrastructure, especially along the Gulf coast. According to a 2018 study, natural gas processing plants in U.S. coastal areas are among the most vulnerable energy infrastructure to inundation by sea level rise.

- March 5, 2019 – In the aftermath of Hurricane Harvey, which brought record rainfall and widespread flooding to Houston and Galveston, the state of Texas and the U.S. Environmental Protection Agency (EPA) prohibited a National Aeronautics and Space Administration (NASA) plane “equipped with the world’s most sophisticated air samplers” to fly over chemical spills, fires, flooded storage tanks, damaged plants, and flooded Superfund sites. Instead, a single-prop plane was used by the EPA to gather information on about two dozen air pollutants, whereas the NASA jet could have analyzed more than 450. At the same time, the Texas governor began a seven-month suspension of state air pollution emissions rules. A subsequent investigation by the Associated Press and the *Houston Chronicle* showed there was “widespread, unreported pollution and environmental damage in the region. The team identified more than 100 storm-related toxic releases, including a cloud of hydrochloric acid that leaked from a damaged pipeline and a gasoline spill from an oil terminal that formed ‘a vapor cloud.’”⁸⁸⁰
- November 30, 2018 – According to the *Miami Herald*, a new Florida Power & Light gas plant, replacing an existing one, will be raised 11.5 feet “to protect from sea level rise, a growing threat caused by emissions from fossil fuel plants.” The region is expected to see 14 to 34 inches of sea level rise by 2062. Testimony at a public hearing, following an

⁸⁸⁰ Rust, S., & Sahagun, L. (2018, March 5). Post-Hurricane Harvey, NASA tried to fly a pollution-spotting plane over Houston. The EPA said no. *Los Angeles Times*. Retrieved from <https://www.latimes.com/local/california/la-me-nasa-jet-epa-hurricane-harvey-20190305-story.html>

outpouring of public opposition to the project, included objections to further investments in fossil fuel projects. “What will you tell residents when the last of their personal possessions wash out to sea and the plant that fuels that tide stands above them?”⁸⁸¹

- November 29, 2018 – Storm protections will not be coming nearly as quickly as the planned tens of billions of dollars in new natural gas processing and chemical facilities along the Texas gulf, explained a collaborative investigative article in the *Texas Tribune*. “Many of the proposed, under-construction or recently built facilities along the Texas Gulf are in areas that felt [Hurricane] Harvey’s bite.” Harvey dropped more rain than any storm on U.S. record and led to chemical spills, contaminant releases to the air, and explosions at oil, gas, and chemical facilities. “Extensive storm modeling by top Texas scientists has shown that if a hurricane hit near the southern end of Galveston Island outside Houston... storm surge would pour into the Port of Houston, dislodging thousands of storage tanks full of crude oil and hazardous chemicals.”⁸⁸²
- September 14, 2018 – In Beaver County, Pennsylvania, a landslide following heavy rains and flooding caused an explosion of a new section of Energy Transfer Partners' Revolution Pipeline one week after it was operational, according to an investigative piece in *Environmental Health News*. The explosion destroyed a house, other structures, and vehicles, and forced evacuations. A few months earlier, a TransCanada natural gas pipeline in Marshall County, West Virginia exploded due to landslide. In its recent permit application, Shell Pipeline Company identified 25 locations prone to landslides along the route of its proposed Falcon Ethane Pipeline through Pennsylvania, Ohio, and West Virginia.⁸⁸³
- September 11, 2018 – Pipeline construction guidelines are based on standards that do not account for recent changes in weather patterns, and flood risks are particularly exacerbated along the Mountain Valley Pipeline route, which passes through extraordinarily rugged terrain. In a mountainous area of Virginia, pipeline construction workers were compelled to rush preparations for catastrophic rain from Hurricane Florence in summer 2018 as the abnormally wet summer overcame efforts to prevent runoff and erosion.⁸⁸⁴

- August 22, 2018 –The state of Texas sought at least \$12 billion, nearly all of it coming from public funds, to build a nearly 60-mile “spine” of concrete seawalls, earthen barriers, floating gates, and steel levees on the Texas Gulf Coast. This region is home to one of the world’s largest concentrations of petrochemical facilities, including most of Texas’ 30 refineries. Facilities that would be protected by this project include those owned by the Saudi-controlled Motiva, Chevron, DuPont, and others. Scaled back from earlier proposals, the current one focused on refineries, according to the Associated Press.⁸⁸⁵
- April 28, 2018 – In their assessment of coastal energy infrastructure at risk along the Gulf Coast, scholars at Louisiana State University concluded that natural gas processing plants in the United States are particularly vulnerable to inundation by sea level rise compared to other energy infrastructure, with up to eight percent of natural gas processing capacity at risk. Tidal flooding is known to be an ancillary effect of sea level rise. Hence, apart from sea level rise itself, “storm surges and flooding from extreme weather-related events often increase the current exposure of these facilities to near-term damage.”⁸⁸⁶ Fifteen natural gas processing plants were in the potential inundation zones of the study’s various sea level rise scenarios, with nine plants projected to be inundated under all three scenarios.
- December 29, 2017 – Flooding was a central theme in an internationally focused review of energy critical infrastructures at risk from climate change. Potential flood impacts on oil and gas infrastructure take many forms: storm surge flooding damaging aboveground fuel storage tanks; flood-related soil erosion exposing buried underground oil and gas pipelines; and inundation of oil refineries. The authors noted that as climate change “leads to an increase in atmospheric moisture content, the likelihood of extreme precipitation and the risk of flooding increase with associated physical impacts” on infrastructure such as power plants and gas pipelines.⁸⁸⁷
- September 15, 2017 – Hurricane Harvey and its resulting flooding affected various parts of metropolitan Houston’s vast oil and gas operations, as well as the Eagle Ford shale region of South Texas. *Reuters* reviewed company reports to the U.S. Coast Guard on the various releases of petrochemicals around the time of Harvey’s hit and subsequent flooding. In addition to more than 22,000 barrels of crude oil, gasoline, diesel, drilling wastewater, and petrochemicals spilled from refineries, storage terminals, and other facilities in the days after the storm, 27 million cubic feet (765,000 cubic meters) of natural gas was released.⁸⁸⁸ Pipeline operators are required to report oil and gas, but not

drilling wastewater, spills to the Texas Railroad Commission. An environmental organization retrieved and listed this data, finding 31 spills at oil and gas wells, storage tanks, and pipelines during the hurricane's flooding. The group notes that though the data contains many "produced water" spills, they are likely underreported since they are not mandatory.⁸⁸⁹ More than half the fracking rigs running in the region were estimated to have shut down. "Given that much of oil and gas activity occurs in areas only accessible via dirt roads, the heavy rainfall usually makes the movement of trucks and supplies much more difficult...The trucking and rail of sand, chemicals, and personnel to the well site will all take more time given the likely nasty condition of many Eagle Ford access roads," according to an energy analyst.⁸⁹⁰

- May 25, 2016 – The removal of photos of flood-related oil spills on a Texas state-run website appears to be an effort to hide visuals that "don't portray the energy business in a flattering light," according to the *El Paso Times* Editorial Board. The photos revealed potential environmental damage caused by flooding at fracking sites.⁸⁹¹ As earlier reported by the *El Paso Times*, many of the photos shot during Texas' recent floods "show swamped wastewater ponds at fracking sites, presumably allowing wastewater to escape into the environment—and potentially into drinking-water supplies."⁸⁹²
- May 1, 2016 – Spring floods across Texas inundated oil wells and fracking sites, tipped over storage tanks, and flushed crude oil and fracking chemicals into rivers, as documented in an Associated Press story that referenced dozens of aerial photographs showing flooded production sites along the Sabine River on the Texas-Louisiana border. (The photographs were later removed from direct public access; see above.) Past president of the American Public Health Association Walter Tsou, MD, called the situation "a potential disaster."⁸⁹³
- June 12, 2015 – At the beginning of 2015, after a month of record-breaking rainfall, Fish and Wildlife Service officials at the Hagerman National Wildlife Refuge in Texas found that floodwaters flowing through oil production well pads in the refuge had inundated dozens of jackpumps, pipelines, and other oil and gas infrastructure, leaving bubbling, oily water and a gassy stench. In 1989, the U.S. Government Accountability Office (GAO) called for "bold action" to address fossil fuel production activities incompatible

with the mission of the refuge system. Subsequent reforms have been exceedingly slow, according to a report from *Greenwire*. In most cases, the Fish and Wildlife Service does not know how much fossil fuel is produced or spilled on refuges, and remediation efforts are inadequate. Severe weather events are expected to increase in frequency and severity as climate change progresses, amplifying flood related concerns.⁸⁹⁴

- June 20, 2014 – The *Coloradoan* reported that Noble Energy storage tanks damaged by spring flooding in Colorado dumped 7,500 gallons of crude oil, fracking chemicals, and fracking wastewater into the Cache la Poudre River, which is both a National Heritage area and a habitat for Colorado’s only self-sustaining population of wild trout. Recent high river flows had undercut the bank where the oil tank was located, which caused the tank to drop and break a valve.⁸⁹⁵
- March 2014 – An extraordinary flood that struck the Front Range of Colorado killed ten people, forced the evacuation of 18,000 more, destroyed more than 1,850 homes, and damaged roads, bridges, and farmland throughout the state. More than 2,650 oil and gas wells and associated facilities were also affected, with 1,614 wells lying directly within the flood impact zone. Many of these storm-damaged facilities and storage tanks leaked uncontrollably. In a later accounting, Matt Lepore, Director of the Colorado Oil and Gas Conservation Commission, estimated the flooding had resulted in the release to the environment of 48,250 gallons of oil or condensate and 43,479 gallons of fracking wastewater from 50 different spill sites across the state. In Colorado, more than 20,850 oil and gas wells lie within 500 feet of a river, stream, or other drainage. According to Director Lepore, setback requirements that keep drilling and fracking operations away from residential areas inadvertently encourage operators to drill in unoccupied floodplains. At the same time, oil and gas operators prefer locations close to supplies of water for use in fracking. These twin factors result in a clustering of drilling and fracking operations in low-lying areas prone to catastrophic flooding.⁸⁹⁶
- 2004-2013 – In at least six of the last ten years (2004, 2005, 2006, 2009, 2011, and 2013), several counties targeted for shale gas drilling in New York State have experienced serious flooding. These include the counties of Albany, Broome, Cattaraugus, Chautauqua, Chenango, Delaware, Erie, Greene, Madison, Orange, Otsego, Schoharie, Sullivan and Ulster. In at least five of the past 10 years (2004, 2005, 2006, 2009 and 2011), floods have exceeded 100-year levels in at least some of the counties.^{897, 898, 899, 900, 901, 902, 903}

- February 7, 2013 – In its 2012 annual report to investors, oil and gas drilling company Noble Energy stated, “Our operations are subject to hazards and risks inherent in the drilling, production and transportation of crude oil and natural gas, including ... flooding which could affect our operations in low-lying areas such as the Marcellus Shale.”⁹⁰⁴
- September 7, 2011 – The New York State Department of Environmental Conservation’s (NYS DEC) draft shale gas drilling plan recommended that drilling be prohibited within 100-year floodplains but acknowledged that many areas in the Delaware and Susquehanna River basins that were affected by flooding in 2004 and 2006 were located outside of officially designated flood zones.⁹⁰⁵ In 2004, 2005, 2006, 2009, and 2011, flooding in New York exceeded 100-year levels in at least some of the counties where drilling and fracking may occur.
- 1992 – In its Generic Environmental Impact Statement (GEIS) for oil and natural gas drilling, which was predicated on conventional drilling, the NYS DEC raised concerns that storage tanks holding drilling wastewater, spent hydraulic fracturing fluid, or other contaminants could be damaged by flooding and leak. At the time, the GEIS called for at least some of these tanks to be properly secured.⁹⁰⁶ Shale gas extraction via horizontal fracking would require many more storage tanks for fracking fluids and wastewater than conventional drilling operations anticipated in 1992 when the agency estimated that oil and gas wells in the state would each require 20,000-80,000 gallons of fracking fluid.⁹⁰⁷ As of 2011, the agency anticipated that high volume, horizontally fracked shale gas wells

Threats to agriculture, soil quality, and forests

Drilling and fracking operations pose risks to farming, soil, and forests. In California, fracking wastewater illegally injected into aquifers threatens crucial irrigation supplies to farmers in a time of severe drought. Fracking wastewater reused for irrigation and livestock watering in California's San Joaquin Valley may contain at least ten known or suspected chemical carcinogens, as well as over a dozen chemicals with no available toxicological data and many unidentified compounds currently classified as "trade secrets." Agricultural uses of wastewater, as well as flowback water spills, raise questions about direct exposure of affected soils, contamination of food crops via bioabsorption through plant roots, and impacts on livestock due to ingestion. Studies and case reports from across the country have highlighted instances of deaths, neurological disorders, aborted pregnancies, and stillbirths in farm animals that have come into contact with wastewater. Additionally, farmers have expressed concern that nearby fracking operations can hurt the perception of agricultural quality and invalidate value-added organic certification. Land use changes and transport of invasive species by drilling and fracking operations have led to documented ecological and monetary harm to soils, forests, and natural areas. In forested areas of Pennsylvania, drilling and fracking operations have greatly reduced canopy covers and thereby diminished the carbon storage capacity of photosynthesizing forest trees. Soil compaction in cleared areas is detrimental to new plant growth and encourages the growth of invasive species.

- September 15, 2018 – Drilling and fracking operations and their associated infrastructure removed a large volume forest canopy in the upper Susquehanna River basin of New York and Pennsylvania from 2006 to 2013. This loss can be considered permanent, according to U.S. Geological Survey (USGS) scientists. Using “lidar” (light detection and ranging) remote sensing technology, the research team assessed three-dimensional volumetric change of forest loss, as opposed to two-dimensional areal loss. Because trees capture carbon dioxide on the surfaces of their canopy leaves during photosynthesis, three-dimensional measurements allow for the assessment of the carbon storage capacity that is sacrificed to gas development via tree removal. The researchers found that a total of 991,326,760m³ of forest canopy was removed by oil and gas activities in the upper Susquehanna River watershed area studied. New York’s loss was “relatively low” because of the state’s fracking moratorium during the study period. The largest losses in forest volumes took place in the Pennsylvania counties of Lycoming, Tioga, Sullivan, Bradford, Wyoming, and Susquehanna. Although timber operations removed more canopy overall, that loss was concentrated in a smaller area.⁹⁰⁹
- September 7, 2018 – Cleared areas around fracking well pads in Pennsylvania state forests are subjected to soil compaction equivalent to that in parking lot construction, according to researchers quoted in a *StateImpact* article. Although not used once the well is in production, these cleared areas are not typically repaired or replanted. Further, this

⁹⁰⁹ Young, J., Maloney, K. O., Slonecker, E. T., & Milheim, L. E., & Siripoonsup, D. (2018). Canopy volume removal from oil and gas development activity in the upper Susquehanna River basin in Pennsylvania and New York (USA): An assessment using lidar data. *Journal of Environmental Management*, 222, 66-75. doi: 10.1016/j.jenvman.2018.05.041

level of compaction is detrimental to new plant growth as the soil has fewer pores to store water or gases needed for plant survival. Experimenting with repair for these areas, Penn State University soil scientist Patrick Drohan said, “A lot of our native species, especially the grasses, are very deeply rooted. So if they can get down through 20 inches of loosened soil they’re going to be able to develop really deep, nice root systems.” Though involved with these experiments and resulting step-by-step repair directions, the Pennsylvania Department of Conservation and Natural Resources is “not proposing to make any of these methods mandatory.”⁹¹⁰

- July 18, 2018 – A USGS study on the Colorado Plateau investigated vegetation cover at inactive well sites. Researchers found that on half of plugged and abandoned oil and gas well sites, the median vegetation cover after five years was 26 percent, while sites with high vegetation cover were dominated by invasive, non-native species. Using satellite-based Landsat time series analysis, the scientists looked at three to six years of vegetation regrowth at 365 well sites in Utah, Colorado, and New Mexico, drilled in 1985 or after and abandoned in 1997 or after. Vegetation recovery generally slowed over time and was related to moisture conditions year to year. Recovery was lower on abandoned well sites in shrublands or evergreen woodlands, which produced only about half the regrowth of well sites in grasslands. The grassland recovery, however, was dominated by invasive annuals such as cheatgrass and Russian thistle. There are currently over 26,000 abandoned and 63,000 active well pads on the Colorado Plateau.⁹¹¹
- July 17, 2018 – A simulation study that applied actual fracking wastewater to local soils in the Denver area investigated how fracking spills might affect the growth of crops. Spills of fracking wastewater resulted in metal contamination at environmentally relevant concentrations as well as a dramatic decrease in water infiltration rate in ways that could have “severe impact on crop production.”⁹¹² Many of the metals studied, including copper, lead, and iron, “met or approached water quality standards and could have important environmental and human health impacts.”
- April 13, 2018 – Grasslands and row crop habitats were most affected in a predictive modeling study of vegetation conversion and landscape fragmentation that would result from future drilling and associated well pad construction in the Eagle Ford Shale. The study, which used “energy production outlook” predictions, found that these impacts increased in spatial extent and magnitude as oil prices increased. The study anticipated that up to 83,000 wells would be drilled through the year 2045 and include as many as 45,500 well pads. In this scenario, between 26,485 and 70,623 hectares (65,446 to 174,513 acres) would undergo vegetative conversion. These results are consistent with findings from related studies. The authors cautioned that their model did not include

future locations of associated infrastructure, such as surface water impoundments and compressor stations. If they were included, “doubling land-change results of this study... would result in a reasonable estimate of overall footprint of all hydrocarbon extractive infrastructure.”⁹¹³

- July 20, 2017 – Penn State University researchers identified a direct correlation between the spread of invasive, non-native plants in Pennsylvania's northern forests and specific aspects of fracking operations. Researchers surveyed 127 Marcellus Shale gas well pads and adjacent access roads in seven state forest districts in the Allegheny National Forest. The study “found that within less than a decade invasive non-native plants have spread to over half of the 127 well pads in our survey, and for the 85% of the pads that were less than 4 years old it occurred in a much shorter period of time.” Gravel shipments and mud on the tires and undercarriages of trucks carry and deposit seeds and propagules of invasive plants. “Given the fact that on average 1235 one-way truck trips delivering fracturing fluid and proppant are required to complete an unconventional well, the potential to transport invasive plant propagules is significant.”⁹¹⁴ “The spread of invasive non-native plants could have long-term negative consequences for the forest ecosystem in a region where the ubiquitous woods provide timbering revenue, wildlife habitat, and ecotourism, warns team member David Mortensen, professor of weed and applied plant ecology.”⁹¹⁵
- May 15, 2017 – By 2015, the annual ecological cost of fracking in the United States reached over \$272 million per year, according to a team of biologists from Hendrix College in Arkansas. They reached this value by estimating the impact of land-use changes on “ecosystem services,” the benefits that natural habitats provide to humans, such as carbon sequestration, flood mitigation, food security, ecotourism revenue, and genetic diversity. Authors considered this estimate to be conservative. In addition, they wrote, “[d]epending on future well-drilling rates, cumulative ecosystem services costs projected to the year 2040 range from US\$9.4 billion to US\$31.9 billion.” Their results showed, “that temperate grassland and deciduous forest are being disproportionately impacted by unconventional oil and gas development. Temperate grasslands are some of the most imperiled ecosystems in North America.” They found “considerable variation in ecosystem services costs between different plays, with Haynesville, Bakken/Three Forks, and Fayetteville showing the highest annual costs.”⁹¹⁶

- April 2, 2017 – Nearly four percent of “core forest” was lost within six years of shale gas development in Lycoming County, Pennsylvania, from 2010 to 2016. Pipelines were the largest contributor to the industry's spatial footprint and were identified as the major fragmenting feature. “Linear infrastructure” (pipelines and roads) led to 3.2 percent loss of core forest, whereas well pad infrastructure (well pad, water impoundment, compressor station, etc.) resulted in 0.9 percent loss of core forests. “Limiting loss of core forest and fragmentation is of particular importance in Pennsylvania and central Appalachia due to potential impacts to area sensitive species.”⁹¹⁷
- November 29, 2016 – A study by engineers and environmental scientists from China, the U.K., and the Republic of Korea investigated the impact of contaminated fracking flowback water on soil health, using soils from representative shale gas areas in China. They also performed a preliminary human health risk assessment of exposure to the arsenic found in such soils. The solutions they tested were representative of flowback water from various stages following a fracked well’s establishment, and their study found that the temporal change in the composition of these wastewaters “leads to different environmental implications.” They tested heavy metal mobility and bioaccessibility, finding that even though mobility was reduced by high ionic strength of flowback water, the metals maintained relatively high bioaccessibility. Soil toxicity moderately increased after a month “aging” with the flowback water treatment. Arsenic, one of the metals included in the testing, is a known human carcinogen and therefore the focus of the human health risk assessment. Results indicated “a low level of cancer risk through exposure via ingestion.”⁹¹⁸
- October 4, 2016 – A research team from Lawrence Berkeley National Laboratory, University of California Berkeley, and University of the Pacific released preliminary results from a first-ever hazard assessment of chemicals used in California oil drilling operations that reuse wastewater for livestock watering and other agricultural purposes in the San Joaquin Valley. This evaluation, compiled as a technical report by PSE Healthy Energy and Lawrence Berkeley National Laboratory, revealed that more than one-third of the 173 chemicals used are classified as trade secret and their identities are therefore unknown. Of the remainder, ten are classified as either carcinogenic or possibly carcinogenic in humans, 22 are classified by the state of California as toxic air contaminants, and 14 had no ecotoxicity or mammalian toxicity data available. “It is difficult or impossible to estimate risks to consumers, farmworkers or the environment,” the authors concluded, “when identification of chemical additives remains in trade secret form and/or lacks toxicity and environmental profile information.”⁹¹⁹

- June 1, 2016 – “Co-contaminant interaction effects” can occur when multiple chemicals are involved in spills of oil and gas wastewater on agricultural soils, according to a study by a Colorado State University research team. Through simulations, researchers analyzed how degradation was affected when combinations of three fracking-related organic chemicals spilled, alone or together: polyethylene glycol, a commonly used surfactant; glutaraldehyde, a biocide to prevent pipe corrosion from microbial activity; and polyacrylamide, a friction reducer. In addition to interactions between the chemicals, they analyzed the role of naturally occurring salts. Results showed that polyethylene glycol surfactants alone can break down in topsoil within 42–71 days, but, in the presence of the biocide glutaraldehyde or salt concentrations typical of fracking wastewater, their biodegradation was impeded or halted altogether. Authors emphasized that the interactions they studied account for only a fraction of the hundreds of fracking chemicals in use, but that their results “show a complex picture of co-contaminant fate and toxicity” that has, so far, been ignored in the regulatory process.⁹²⁰
- December 12, 2015 – A research team at the University of Aberdeen found high levels of selenium, molybdenum, and arsenic in rock samples collected from a region in northern England that has been targeted for fracking. The finding is important due to the possible risk that these toxic elements will be released into groundwater during shale gas operations. Selenium poisoning has occurred among Irish horses confined to pastures underlain by black shale. While small amounts of selenium are essential for metabolism, high levels (which, in the case of human consumption, is above 400 µg/day) are toxic. Possible consequences include neurotoxicity, cancer and diabetes.⁹²¹
- November 23, 2015 – Gas-related impacts on Pennsylvania farmers may include pipelines criss-crossing fields and forests, as well as jeopardization of organic certification, according to a report covering a State Agriculture Department spokesman’s presentation, on the Potter County government website. The spokesman said, “steps should be taken to steer this development in ways that diminish impact on soil quality and fragmentation.” “With trees and other vegetation being cleared from pipeline rights-of-way, he noted, it’s important for the acreage to be replanted with plant species that are beneficial to agriculture—pollinating plants, as an example.”⁹²²
- October 24, 2015 – More than 180 million gallons of wastewater from oil and gas operations spilled from 2009 to 2014, according to an Associated Press analysis of data

from leading oil- and gas-producing states (Texas, North Dakota, California, Alaska, Colorado, New Mexico, Oklahoma, Wyoming, Kansas, Utah and Montana). A *Dallas Morning News* report focused on how the resulting contamination of groundwater and soils has affected agricultural and ranching. In one case, wastewater from pits seeped beneath a cotton and nut farm near Bakersfield, California and forced the grower to remove 2,000 acres from production. In western Texas, pipeline failures and illegal dumping of frack waste contaminated ranches and pastures.⁹²³

- May 2, 2015 – The *Los Angeles Times* reported that farmers in Kern County, California purchased over 21 million gallons per day of treated oil field wastewater to use for crop irrigation. The article identified lingering questions about chemicals remaining after treatment and their potential impact both on the crops and those who consume them. Independent testing identified chemicals including acetone and methylene chloride, along with oil, in the treated irrigation water.⁹²⁴ Acetone and methylene chloride are powerful industrial solvents that are highly toxic to humans, and samples of the wastewater contained concentrations of both that were higher than those seen at oil spill disaster sites. (Chevron’s own report confirmed the presence of acetone, benzene, and xylene, though in lesser concentrations; Chevron did not appear to test for methylene chloride.⁹²⁵) Broader testing requirements involving chemicals covered under California’s new fracking disclosure regulations went into effect June 15, 2015.⁹²⁶
- April 24, 2015 – Unconventional technologies in gas and oil extraction facilitated the drilling of an average of 50,000 new fractured wells per year in North America over the past 15 years. An interdisciplinary study published in *Science* demonstrated that the accumulating land degradation has resulted in continent-wide impacts, as measured by the reduced amount of carbon absorbed by plants and accumulated as biomass. This is a robust metric of essential ecosystem services, such as food production, biodiversity, and wildlife habitat, and its loss “is likely long-lasting and potentially permanent.” The land area occupied by well pads, roads, and storage facilities built during this period is approximately three million hectares, roughly the land area of three Yellowstone National Parks. The authors concluded that new approaches to land use planning and policy are “necessary to achieve energy policies that minimize ecosystem service losses.”⁹²⁷

- January 26, 2015 – Two Colorado scientists performed a detailed analysis of vegetative patterns—followed chronologically—over a selected group of well pads in Colorado managed by the U.S. Bureau of Land Management, including two undisturbed reference sites. They documented the disturbance of plant and soil systems linked to contemporary oil and gas well pad construction, and found that none of the oil and gas well pads included in the study returned to pre-drilling condition, even after 20-50 years. Full restoration may require decades of intensive effort.⁹²⁸
- October 14, 2014 – State documents obtained by the Center for Biological Diversity show that almost three billion gallons of fracking wastewater have been illegally dumped into central California aquifers that supply drinking water and farming irrigation. The California Water Board confirmed that several oil companies used at least nine of 11 injection wells that connect with high-quality water sources for disposal of fracking wastewater, which included high levels of arsenic, thallium, and nitrates. The California Division of Oil, Gas and Geothermal Resources has shut down 11 oil field injection wells and is scrutinizing almost 100 others for posing a “danger to life, health, property, and natural resources.” At least one farming company has sued oil producers in part for contaminating groundwater that farms use for irrigation.⁹²⁹
- September 6, 2014 – *Al Jazeera America* examined the challenges that North Dakota farmers are facing in light of wastewater spills from oil and gas development. Notably, in heavily drilled Bottineau County, some levels of chloride, from sites where an estimated 16,800-25,200 gallons of wastewater had seeped into the ground, were so high that they exceeded the levels measurable with the North Dakota Department of Health’s test strips. State records, testimonies from oil workers and various residents, and the decades-long failure of contaminated fields to produce crops indicate that wastewater spills are a significant hazard in the current fracking boom.⁹³⁰
- August 6, 2014 – The Pennsylvania Department of Environmental Protection (PA DEP) found that leaks of fracking wastewater from three impoundments contaminated soil and groundwater. The findings prompted the state to issue a violation and increase testing.⁹³¹
- August 5, 2014 – Michelle Bamberger, a veterinarian and researcher, and Robert Oswald, a professor of molecular medicine at Cornell University, published a book that describes their research into the impacts of drilling and fracking on agriculture and animal health. They detail results of 24 case studies from six gas drilling states, including follow-up on

cases they previously published in the peer-reviewed literature, raising concerns about the effects of drilling and fracking on agriculture and the health of animals.⁹³²

- August 1, 2014 – At least 19,000 gallons of hydrochloric acid spilled during completion of a fracking well on an alfalfa farm in Kingfisher County, Oklahoma. The Oklahoma Corporation Commission reported concerns about rain pushing chemical runoff into a nearby creek that flows into the town of Hennessey’s water system. The responsible company, Blake Production, planned to pay for the alfalfa crop for six years. The landowner and a neighbor were pursuing litigation.⁹³³
- May 4, 2014 – In an analysis of state data from Colorado, the *Denver Post* reported that fracking related to oil and gas drilling is putting soil quality and farmlands at risk due to significant amounts of toxic fluids penetrating the soil. According to report, 578 spills were reported in 2013, which means that, on average in the state, a gallon of toxic liquid penetrates the ground every eight minutes. Colorado State University soil scientist Eugene Kelly, said that the overall impact of the oil and gas boom “is like a death sentence for soil.”⁹³⁴
- November 28, 2012 – In conjunction with the Food & Environment Reporting Network, *The Nation* reported that serious risks to agriculture caused by fracking are increasing across the country and linked these concerns to risks to human health.⁹³⁵
- January 2012 – A study of gas drilling’s impacts on human and animal health concluded that the drilling process may lead to health problems. The study reported and analyzed a number of case studies, including dead and sick animals in several states that had been exposed to drilling or hydraulic fracturing fluids, wastewater, or contaminated ground or surface water.⁹³⁶ The researchers cited 24 cases in six states where animals and their owners were potentially affected by gas drilling. In one case, a farmer separated 96 head of cattle into three areas, one along a creek where fracking wastewater was allegedly dumped and the remainder in fields without access to the contaminated creek; the farmer found that, of the 60 head exposed to the creek, 21 died and 16 failed to produce, whereas the unexposed cattle experienced no unusual health problems. In another case, a farmer reported that of 140 head of cattle exposed to fracking wastewater, about 70 died, and there was a high incidence of stillborn and stunted calves in the remaining cattle.⁹³⁷

- January 2011 – U.S. Forest Service researchers reported dramatic negative effects on vegetation caused by the drilling and fracking of a natural gas well in an experimental forest in northeastern West Virginia. In June 2008, the researchers found browning of foliage near the well pad, a lack of ground foliage, and that many trees nearby had dropped their foliage. They attributed these impacts to the loss of control of the wellbore on May 29, 2008, which caused an aerial release of materials from the well. Trees showed no apparent symptoms the following summer. However, the researchers also found “dramatic impacts on vegetation” where drilling and fracking wastewater had been sprayed on the land as a disposal technique following completion of the well. Just after the spraying of approximately 60,000 gallons of wastewater at the first disposal site, the Forest Service researchers found 115 damaged trees and other evidence of harm. This figure grew to 147 trees almost a year later. At a second site, where about 20,000 gallons of wastewater was sprayed, the damage was less dramatic, yet the researchers still found “considerable leaf browning and mortality of young northern red oak seedlings.” The researchers concluded that the spraying of the drilling fluids resulted in an “extreme” dose of chlorides to the forest.⁹³⁸
- May 2010 – Pennsylvania’s Department of Agriculture quarantined 28 cows in Tioga County after the animals wandered through a spill of drilling wastewater and may have ingested some of it. The Department was concerned that beef eventually produced from the cows could be contaminated as a result of any exposure. In May 2011, only ten yearlings were still quarantined, but the farmer who owned the cows, Carol Johnson, told National Public Radio that of 17 calves born to the quarantined cows in the spring of 2011, only six survived, and many of the calves that were lost were stillborn. “They were born dead or extremely weak. It’s highly unusual,” she said, continuing, “I might lose one or two calves a year, but I don’t lose eight out of eleven.”⁹³⁹
- March 2010 – A Pennsylvania State Extension analysis of dairy farms in the state found a decline in the number of dairy cows in areas where fracking was prevalent. Pennsylvania counties that had both more than 10,000 dairy cows and more than 150 Marcellus Shale wells experienced a 16-percent decline in dairy cows between 2007 and 2010.⁹⁴⁰
- April 28, 2009 – Seventeen cows in Caddo Parish, Louisiana died within one hour after apparently ingesting hydraulic fracturing fluids spilled at a well that was being fractured. “It seemed obvious the cattle had died acutely from an ingested toxin that had drained

from the ‘fracking’ operation going on at the property,” Mike Barrington, a state veterinarian said in a document obtained from the state Department of Environmental Quality by the *Times-Picayune*.^{941, 942}

- August 1977 – A paper in the *Journal of Arboriculture* described how natural gas leaks in soil can damage plants and crops. The paper notes that vegetation dies in the vicinity of natural gas leaks. Due to the oxidation of methane by methane-consuming bacteria, gas leaks drive down the oxygen concentration to extremely low levels and cause carbon dioxide concentration to rise. The resulting low oxygen concentration is the greatest contributing factor in the death of trees and other vegetation near natural gas leaks.⁹⁴³

Threats to the climate system

Natural gas is not a climate-friendly fuel. Methane, which escapes from all parts of the natural gas extraction and distribution system, is a powerful greenhouse gas that traps 86 times more heat than carbon dioxide over a 20-year time frame. According to the best available evidence, fuel-switching that replaces coal with natural gas to generate electricity offers no clear climate benefits and likely represents a step backwards. As is now documented in many studies, fugitive methane emissions from U.S. drilling and fracking operations, storage, and ancillary infrastructure are higher than previously supposed. A significant proportion of these leaks are not preventable through engineering fixes. Indeed, some represent intentional venting during routine maintenance or during attempts to control pressure and prevent explosions during malfunctions. Venting takes place at all points along the supply chain, from well pads, pipelines, and compressor stations to liquefied natural gas (LNG) export terminals. A 2018 analysis of methane emissions from the U.S. oil and gas supply chain that used a combination of measurement methodologies found leakage rates 60 percent higher than reported by the U.S. Environmental Protection Agency (EPA) and concluded that natural gas is just as damaging as coal for the climate over a 20-year time frame. Collectively, a range of studies disprove the claim that natural gas is a transitional “bridge” fuel that can lower greenhouse gas emissions while renewable energy solutions are developed.

A sharp rise in global atmospheric methane concentrations began in 2007 and has accelerated since 2014. The causes for this spike are not yet fully understood and likely include both biogenic sources (livestock, agriculture, wetlands, landfills, forest fires) and fossil fuel sources. As both satellite and ground measurements reveal, U.S. methane emissions are responsible for 30-60 percent of the recent upsurge in global atmospheric methane concentrations. Most of this excess methane appears to represent fugitive emissions from U.S. oil and gas operations.

Many lines of evidence point to the important role of unconventional oil and gas extraction in driving greenhouse gas emissions upward. These include the atmospheric pattern of increased methane concentrations directly over intensively fracked areas of the United States; sharp upticks in global methane and co-occurring ethane levels that correspond to the advent of the U.S. fracking boom; and documentation of large pulses of methane released from storage facilities and other “super-emitting” sites. A major study from the National Aeronautics and Space Administration (NASA) in 2017 found that methane from biomass sources, such as fires, decreased over the time period 2001-2016 while fossil fuel sources of methane increased. Further, the widely touted claim that the U.S. fracking boom has contributed to recent declines in carbon dioxide emissions in the United States has been invalidated by research showing that almost all of the reductions in CO₂ emissions between 2007 and 2009 were the result of economic recession rather than coal-to-gas fuel switching. Other lines of research show that expanded use of natural gas impedes rather than encourages investments in, and deployment of, renewable energy infrastructure. In sum, fracking, as a major driver of rising methane emissions, is incompatible with climate stability and the goal of rapid decarbonization that it requires.

- March 12, 2019 – Using aircraft, a team of researchers from multiple universities and institutions estimated emissions from both coal mines and shale gas wells in southwestern Pennsylvania. For coal, their results largely aligned with EPA estimates. However, for natural gas wells, emissions were five times higher than EPA figures. Because the volume of gas extracted per well is higher than in other shale basins, production-scaled methane emissions were still comparatively low, with carbon dioxide emissions from combustion remaining the dominant source of greenhouse gas emissions.⁹⁴⁴
- March 7, 2019 – Methane is a very strong greenhouse gas, with 120 times the power to trap heat than an equivalent amount of carbon dioxide. However, methane persists in the atmosphere for an average of only 12.4 years whereas carbon dioxide can linger for a century or more. Using a combination of approaches, a London team assessed the contribution of natural gas extraction to future greenhouse gas emissions in the United States, taking into account timing as well as magnitude of emissions and changing prices. They found that methane emitted further into the future—and therefore closer to the year where climate stabilization needs to take place—has a disproportionately large bearing on the overall climate impact of drilling and fracking activities, with long-lived gas fields having the most effect. “A key finding of this study is that the environmental and economic consequences of emissions are likely to rise with the age of a field, thus exposing long-lived assets to the greatest potential losses....Overall, our results suggest that future cumulative greenhouse gas emissions from existing US [gas] fields have a significant short-medium climate impact.” The authors recommend carbon pricing as a strategy to shorten the lifetime of long-lived gas fields. They also report that 40 percent of carbon dioxide output from natural gas is directly related to drilling activities.⁹⁴⁵
- February 28, 2019 – Australia’s LNG export industry contributed significantly to rising carbon emissions from that country in the 12 months prior to September 2018, according to Australia’s National Greenhouse Gas Inventory. Emissions from power plants fell during this same time period as the result of a 31 percent jump in renewable energy serving eastern Australia. These declines, however, were more than offset by soaring increases in industrial and fugitive emissions from Australia’s LNG plants.⁹⁴⁶ LNG exports rose by one fifth in 2018.⁹⁴⁷ This jump represents the third consecutive year of

rising greenhouse gas emissions from Australia. The expansion in LNG production and export was identified as the major contributor to this trend.⁹⁴⁸

- February 27, 2019 – An international team investigated the climate and the public health harms attributable to fossil fuel combustion. Their global model estimated an avoidable excess mortality rate of 3.61 million deaths per year from air pollution alone. Air pollution also chemically reacts with dust to create aerosols that disrupt the hydrologic cycle and impede rainfall patterns. If fossil fuel burning ended, not only would deaths due to air pollution be avoided but additional lives would be saved as water and food security improved in densely populated areas of India, northern China, and central America. In sum, “a rapid phaseout of fossil fuel-related emissions and major reductions of other anthropogenic sources are needed to save millions of lives, restore aerosol-perturbed rainfall patterns, and limit global warming to 2 C°.”⁹⁴⁹
- February 12, 2019 – In southeastern Saskatchewan, Canada, conventional gas and oil drilling takes place side by side with unconventional drilling via fracking. In a first study of its kind, a St. Francis Xavier University research team directly compared methane emissions from both types of co-located wells. By conducting truck-based air sampling downwind from 645 conventional wells and 289 unconventional wells, the team found that 28 percent of conventional wells leaked methane compared to 32 percent of fracked wells. The bigger difference was in measures of mean emission intensities from the wells that were leaking. Leaking fracked wells emitted nearly three times as much methane (59 cubic meters of methane per day) as leaking conventional wells (20 cubic meters of methane per day). “Our results showed that unconventional sites in southeastern Saskatchewan emit about as often as nearby conventional sites, but with somewhat greater severity.”⁹⁵⁰
- February 5, 2019 – A team led by University of Maryland researchers conducted aircraft sampling in 2015 to assess leakage from drilling and fracking operations in the southwestern Marcellus Shale. Coalbeds were the likely source of more than 70 percent of the emitted methane. Of the methane that likely arose from shale gas wells, the estimated mean emission rate was 1.1 percent of the total natural gas extraction. These results were consistent with (but at the low end of) estimates determined by previous observational studies in this region. They indicate that the climate impact of natural gas combustion falls below that of coal. Nevertheless, the full range includes values up to 3.5

percent, which falls above the break-even point with coal over a 20-year time span.⁹⁵¹

- February 5, 2019 – Sampling air from remote locations all over the world, an international team of atmospheric scientists confirmed a sharp rise in global atmospheric methane. This spike began in 2007 and has accelerated since 2014. The causes for the increase are not fully understood. The research team also documented, over the same time period, a shift in the carbon isotope ratio, which may signal a shift in the relative proportions of emissions from different sources. (These various methane sources include, for example, gas leaks, microbes, livestock, landfills, biomass burning.) Alternatively—or additionally—it may signal a decline in the oxidative capacity of the atmosphere, which breaks apart methane molecules. A change in the rate of methane destruction can also change the carbon isotope ratio. Either way, a sharp, ongoing increase in global methane concentrations was not predicted by the future greenhouse gas scenarios that were incorporated into the targets of the Paris Agreement. If the current increase continues, the goals of that treaty could be out of reach. “There is now urgent need to reduce methane emissions, especially from the fossil fuel industry... anthropogenic methane emissions are relatively very large and thus offer attractive targets for rapid reduction, which are essential if the Paris Agreement aims are to be attained.”⁹⁵²
- February 4, 2019 – Permafrost is soil that remains frozen year-round. If it thaws, microbes turn the carbon contained in the soil into carbon dioxide and methane. Because such a vast amount of carbon is held in permafrost, warming Arctic temperatures may release a large pulse of climate-destabilizing methane and so trigger an uncontrolled positive feedback loop. A study by an international team looked at the fate of permafrost under different scenarios of greenhouse gas mitigation, including some in which no progress is made toward decreasing fossil fuel-based emissions and others in which the targets of the Paris Agreement are met. In their analysis, the team determined the highest level of natural methane emissions that can be released from the Arctic by 2100. This level is considerably lower than likely anthropogenic methane emission levels over the same time period, which indicates that human-made emissions can be reduced sufficiently to limit methane-causing climate warming by 2100 even if the permafrost undergoes an uncontrolled emission feedback—but only if a committed, global effort to reduce fossil fuel use takes place very soon.⁹⁵³ In a press release about this research, one of the authors of the study, Lena Höglund-Isaksson, said, “It is important to put the two estimates alongside each other to point out how important it is to urgently address methane emissions from human activities, in particular through a phase out of fossil fuels. It is important for everyone concerned about global warming to know that humans are the main source of methane emissions and that if we can control humans’ release of

methane, the problem of methane release from the thawing Arctic tundra is likely to remain manageable.”⁹⁵⁴

- December 4, 2018 – Research firm Rystad Energy reported that gas flaring in the west Texas Permian Basin has doubled since 2017. Oil wells in the region pump out large volumes of associated natural gas. Without pipelines to bring the gas to burner tips, and in order to maintain the rapid pace of oil drilling, operators simply waste the gas—worth more than \$1 million per day—by burning it off in flare stacks. Flaring permits are limited to 45 days but are now routinely extended for up to six continuous months.⁹⁵⁵
- November 23, 2018 – In a report commissioned by the Obama administration in 2016, the U.S. Geological Survey (USGS) provided estimates on greenhouse gas emissions associated with the extraction and combustion of fossil fuels produced from federal lands. Between 2005 and 2014, fully one-quarter of all U.S. carbon emissions come from fossil fuels that were extracted from public lands. The report found that forests on federal lands can offset some of these emissions but only by 15 percent. Fossil fuels are extracted from public lands in 28 states with more than half the total carbon emissions coming from Wyoming.^{956, 957}
- October 29, 2018 – The Basin Methane Reconciliation Study was a large-scale field investigation that brought together more than 80 scientists from multiple institutions. They examined why different methods of accounting for methane emissions from natural gas drilling sites vary so widely across the United States. The study took place in 2015 in Arkansas’ Arkoma Basin and utilized both bottom-up and top-down approaches, which is to say, measurements were taken on the ground at selected facilities as well as in the atmosphere over the region, via aircraft. This type of concurrent dual analysis had never been attempted before. The study revealed spikes of high emissions that occur during daytime maintenance operations, as when, for example, liquids are being removed from a well and natural gas is freely vented into the air for the duration of that process. The high temporal variability and episodic nature of methane emissions likely explain the persistent gap between the two accounting methods and mean that researchers who attempt to determine how much methane is escaping from drilling and fracking operations require “detailed activity data, unfettered and unbiased site access, and time-resolved operations data.” This type of study necessarily requires cooperation with

industry employees.⁹⁵⁸

- August 1, 2018 – The Groningen natural gas field in the northern Netherlands is one of Europe’s major gas fields where extraction, gas processing, and gas storage all take place. It is also a region with intensive agriculture and cattle operations. An international research team investigated methane emissions there with the intent of distinguishing between methane from fossil fuel sources and methane arising from livestock, wetlands, and agriculture. Using both ground and aircraft measurements, the researchers determined that emissions from oil and gas operations account for 20 percent of regional methane, with the remainder from biogenic sources. That figure for fossil fuel sources is, nevertheless, ten times higher than the 1.9 percent that was estimated by previous inventories. Ground-based measurements at extraction, processing, and storage sites found low emission rates compared to gas production facilities in the United States. Production volume was a poor predictor of emission rates. Even wells with no production still had emissions.⁹⁵⁹
- August 1, 2018 – California’s climate goals call for an 80 percent reduction in emissions by 2050. With this goal in mind, a Lawrence Berkeley National Laboratory team set out to estimate what fraction of California’s greenhouse gas emissions represent methane emissions from residential homes, including leakage from gas pipes, stovetops, combustion appliance pilot lights, and forced air furnaces. Total methane emissions from California homes represent 15 percent of the total emissions from the natural gas sector in California and represent two percent of the state’s total methane emissions, as calculated in the 2015 state inventory. The team also found that emissions from pilot lights constitute a significant fraction as do flames in domestic hot water heaters. “While methane emissions from houses are small compared to most sources, California’s ambitious goals...suggest value in testing and repairing obvious leaks in residential gas lines, modernizing combustion appliances to move away from pilot lights, and gradually increasing the use of non-fossil fuel energy sources for residential space and hot water heating and cooking.”⁹⁶⁰
- July 10, 2018 – In 2015, as part of a follow-up study, a research team used helicopters to measure methane emission patterns at 353 well pads in North Dakota’s Bakken Shale that had been surveyed in the same way in 2014. In the interim, 21 newly producing well pads were added to the sampling area. They found that the individual well pads that emitted methane in 2014 were far more likely to be still emitting in 2015 than would be expected by chance alone. The reasons for this persistent leaking were not identified but potentially

include tanks without vapor recovery systems, overpressurization, undersized flaring systems, stuck or clogged valves, and “poorly designed equipment.” Altogether, researchers quantified 33 plumes of methane and ethane arising from these well pads.⁹⁶¹

- June 21, 2018 – An analysis of methane leaks from the U.S. oil and gas supply chain found that natural gas is just as damaging as coal for the climate over a 20-year time frame. This study combined on-the-ground measurements of leaks at selected facilities (bottom-up methods) with data collected from the atmosphere via aircraft (top-down methods). Based on the results, the authors estimated that roughly 2.3 percent of all the natural gas extracted in the United States escapes into the air. This estimated level of leakage was 60 percent higher than the EPA’s estimate of 1.4 percent. The authors believe their emissions estimate is the more accurate because they used helicopters to capture episodic releases of large plumes of methane caused by “abnormal operating conditions” and “failure-prone systems” that were likely missed by the sampling methods used for EPA’s greenhouse gas inventory. Liquid storage tank hatches and vents were the source of most of acute incidents.⁹⁶²
- December 20, 2017 – A major study led by NASA researchers concluded. that fossil fuel sources are driving the sharp uptick in global atmospheric concentrations of methane since 2006. Using satellite measurements and isotopic analysis, the team showed that methane from biomass sources, such as fires, decreased over the time period 2001-2016 while fossil fuel sources of methane increased. These findings helped reconcile conflicting results from other previous studies.⁹⁶³
- October 17, 2017 – Using planes, an international team of researchers measured regional airborne methane and ethane emission rates from the Alberta oil and gas fields in Canada. They compared these results to emissions reported by the industries themselves, as part of an accounting system that requires operators to report flaring and venting volumes, and found large discrepancies. Based on the amounts of methane and ethane detected in the atmosphere above the oil and gas fields, the reported industry emissions in this region should be 2.5 ± 0.5 times higher. Such large discrepancies between actual methane emissions and industry-provided data represent a “reporting gap” and present a critical challenge when determining policy. Proposed regulations in Canada currently call for reducing methane emissions from Canadian fracking operations by 45 percent. However, these data indicate that most of the methane emissions from these operations arise from

fugitive leaks that are not being measured at all and/or from episodes of unreported venting.⁹⁶⁴

- July 18, 2017 – A team of 15 climate scientists led by James Hansen at Columbia University conducted a study on the growth rate of greenhouse gas climate forcing, which has accelerated by 20 percent in the past decade. (Climate forcing is the difference between the amount of the sun’s energy that is absorbed by the Earth and amount that radiates back into space.) The authors note that methane (CH₄) is the largest climate-forcing gas after carbon dioxide. With an atmospheric lifetime of only about ten years, “there is potential to reduce climate forcing rapidly if CH₄ sources are reduced.” However, “there is a danger of increased leakage with expanded shale gas extraction.” Noting that the speed of ice sheet melting and sea level rise are difficult to predict, the authors assert that targets for limiting global warming should aim to keep global temperatures close to the preindustrial Holocene range rather than allow them to rise to those found during the prior Eemian period, when sea levels were 6-9 meters higher than today. Such targets require immediate phase-out of fossil fuel emissions, along with profound changes in farming and forestry practices. A delay in taking these measures to minimize irreversible climate impacts means that the next generation will be required to undertake risky, expensive, large-scale CO₂ extraction practices, such as carbon capture. “If high fossil fuel emissions continue, a great burden will be placed on the young. . . . Continued high fossil fuel emissions unarguably sentences young people to either a massive, implausible cleanup or growing deleterious climate impacts or both.”⁹⁶⁵
- July 8, 2017 – An investigative report from the Inter Press Service News Agency examined the climate impacts of methane emissions from Mexico, which is sixth among the world’s nations in technically recoverable shale gas reserves (after China, Argentina, Algeria, the United States, and Canada). Mexico’s current energy policy, introduced in 2014, emphasizes the exploitation of shale gas using fracking. Using data from the state-owned energy company Petroleos Mexicanos (PEMEX), the Inter Press Service story documents that as of 2017, more than 900 wells, located in six of Mexico’s 32 states, have been drilled and fracked. High volumes of methane are emitted during venting, and methane emissions have been increasing sharply. In 2016, the total methane emissions from Mexico’s PEMEX Exploration and Production operations were 641,517 metric tons, 38 percent higher than the previous year. According to researcher Ramón Torres, of the National Autonomous University of Mexico, who is quoted in the story, “Current regulations are based on best practices, but the philosophy of environmental protection has been abandoned. Exploitation is deepening inequities in a negative way, such as environmental impact. It is irresponsible to auction reserves without a proper evaluation of environmental and social impacts.”⁹⁶⁶

- June 19, 2017 – A study that measured methane emissions from various components of drilling and fracking equipment on well pads located in four different shale basins in Colorado, Utah, Arkansas, and Wyoming found widely varying results. In Colorado and Utah, a small percentage of well pads leaked the vast majority of methane, whereas leakage was more equitably distributed among wells in Wyoming. The research team also found variations that were dependent on oil/gas/water content as well as on the numbers of wells per well pad. In sum, emissions from well pads contributed significantly to basin-wide methane emissions but varied depending on location. [Note: the authors identify XTO Energy as a cost share partner in this study.]⁹⁶⁷
- April 18, 2017 – San Juan Basin in the four-corner region of Utah, Arizona, New Mexico, and Colorado, is one of the largest coal-bed methane producing regions in North America. Between 2003 and 2015, natural gas production declined, and yet, as revealed by atmospheric sampling from aircraft flying over the basin, methane emissions did not decrease during this same time period. These results confirm earlier findings from a satellite study that also showed no declines in regional methane concentrations in spite of significant declines in natural gas production. According to the authors, the likely explanation for the region’s persistent, elevated methane levels is increased oil drilling in the basin.⁹⁶⁸
- February 9, 2017 – Using ground-based monitoring methods, a team led by Drexel University researchers monitored a range of emissions, including methane, in two intensively drilled regions of the Marcellus Shale basin in Pennsylvania. The goal was to understand the concentrations and sources of relevant air pollutants that had previously been reported as impacts of drilling and fracking operations. Airborne methane concentrations were higher in southwestern Pennsylvania as compared to northeastern Pennsylvania. The authors conclude that urban-like levels of air pollutants in rural Pennsylvania are likely due to emissions from oil and gas operations in the Marcellus Shale basin.⁹⁶⁹
- January 9, 2017 – A modeling study found that short-lived greenhouse gases, such as methane, contribute to thermal expansion of the ocean over much longer time scales than their brief atmospheric lifetimes might otherwise predict. “Actions taken to reduce

emissions of short-lived gases could mitigate centuries of additional future sea-level rise.”⁹⁷⁰

- December 12, 2016 – As part of the interdisciplinary Global Carbon Project, a consortium of scientists undertook a meta-analysis that synthesizes many hundreds of individual studies in order to better understand the global methane cycle. Integrating atmospheric measurements with ground-based data, the researchers found more uncertainty in the emissions from natural sources than from human activities. For the 2003–2012 decade, global methane emissions were 558 teragrams per year (range of 540–568), with 60 percent of global methane emissions attributed to anthropogenic sources of all kinds and with a significant contribution (likely at least 39 percent) from oil and gas production operations.⁹⁷¹
- December 12, 2016 – An editorial published in *Environmental Research Letters* by an international team of scientists urges immediate attention to quantify and reduce methane emissions. “Unlike CO₂, atmospheric methane concentrations are rising faster than at any time in the past two decades and, since 2014, are now approaching the most greenhouse-gas-intensive scenarios.” The authors present methods of evaluating anthropogenic and biogenic sources of methane, as from agricultural practices and project future methane emissions.⁹⁷²
- November 8, 2016 – The government of Scotland released a report confirming that the pursuit of unconventional oil and gas extraction would make more difficult the nation’s goal of meeting its climate targets on greenhouse gas emissions.⁹⁷³
- November 1, 2016 – A life cycle analysis of greenhouse gas emissions from fracking operations in the Marcellus Shale region found that upstream activities associated with the use and transportation of chemicals, water, and sand mining contributed relatively lower emissions than downstream phases of the fracking process, which include gas combustion, methane leakage, venting, and flaring.⁹⁷⁴
- October 5, 2016 – A new inventory of worldwide methane emissions from various sources finds that methane emissions from the fossil fuel industry are 20-60 percent

higher than previously thought.⁹⁷⁵ This discovery, based on isotopic fingerprinting of methane sources, has prompted researchers to call for revisions to current climate prediction models and for a renewed emphasis on reducing methane emissions as a necessary tool for combating climate change.⁹⁷⁶

- September 26, 2016 – In ratifying the Paris Climate Agreement, the United States pledged to reduce its greenhouse gas emissions 26-28 percent by 2025 as compared to 2005 levels. A research team from Lawrence Berkeley National Laboratory found that the United States is on track to miss this target, in large part because of soaring methane emissions.^{977, 978}
- September 12, 2016 – Using isotopic analysis and archived air samples collected from 1977 to 1998, as well as more contemporary data, a team of researchers from Oregon presented “strong evidence” that methane emissions from fossil fuel sectors were approximately constant in the 1980s and 1990s but then increased significantly between 2000 and 2009. Over the same time period, methane emissions from biomass burning, rice cultivation, and wetlands decreased. These results contradict the findings of earlier studies that used atmospheric ethane as a marker for methane and had concluded that fugitive fossil fuel emissions fell during much of that period. (More recent studies show that ethane emissions are increasing again.)^{979, 980, 981}
- July 11, 2016 – A group of 130 environmental and health organizations signed a formal complaint with the Inspector General of the U.S. Environmental Protection Agency (EPA) about a pivotal 2013 study that was published in the *Proceedings of the National Academies of Sciences* and which was led by University of Texas chemist David T. Allen. The letter accused Allen of “systemic fraud, waste, and abuse” for his reliance on an inaccurate measurement device that was known to underestimate methane levels.

Partially funded by the oil industry, Allen's study reported very low methane emission rates as part of a large survey of 190 drilling and fracking sites across the nation. That flawed study was influential, said complainants, in preventing EPA from recognizing the magnitude of methane leakage from drilling and fracking operations.⁹⁸² (See also the entry below for March 24, 2015.)

- June 17, 2016 – A comparative assessment of emerging methods for measuring methane emissions from different sources recommends combining analytic methods with chemical mass balance (CMB) methods. The CMB system is currently used in the Barnett Shale oil and gas production region in Texas as an approach to tracing methane emissions back to their sources.⁹⁸³
- May 25, 2016 – As part of the first field study to directly measure methane emissions from the heavily drilled Bakken Shale formation in northwestern North Dakota, a team led by atmospheric chemist Jeff Peischl at NOAA flew research aircraft over the region in May 2014. The researchers derived a methane emission rate of 275,000 tons of methane per year, which is similar to the rate of methane leakage in the Front Range area of Colorado but significantly lower than previous studies of the Bakken area that relied on satellite remote sensing data during an earlier time period (2006-2011). Analyzing the chemical composition of air samples, the NOAA team determined that almost all of the methane originated with oil and gas operations, rather than with natural or agricultural sources, and estimated a leakage rate of 4.2-8.4 percent.⁹⁸⁴ Scaled to production, this emission rate is slightly lower than that estimated by EPA in its recently revised inventory.^{985, 986} (See April 15, 2016 entry below.)
- April 15, 2016 – In its 21st annual greenhouse gas inventory, which includes 2014 data, the EPA increased its leakage assessment from oil and gas operations by 34 percent. For oil production alone, the EPA more than doubled its estimates of methane emissions. Further, in an admission that the agency had been historically underestimating methane leaks, the EPA also retroactively increased estimates of past emissions from the fossil

fuel sector as expressed in prior inventories.^{987, 988} In an accompanying news release, the agency said, “Data on oil and gas show that methane emissions from the sector are higher than previously estimated. The oil and gas sector is the largest emitting-sector for methane and accounts for a third of total U.S. methane emissions.”⁹⁸⁹ Past EPA inventories had identified livestock as the number one source of U.S. methane. These annual inventories fulfill the EPA’s obligations under the United Nations Framework Convention on Climate Change, signed and ratified by the United States in 1992, and attempt to identify and quantify U.S. anthropogenic sources and sinks of greenhouse gases for the time period 1990 and forward. The upward revision in both past and current inventories is a reflection of changing methodologies for measuring methane leaks.⁹⁹⁰ Older methods included the incorporation of “bottom-up” data supplied by the oil and gas industry, without attention to high-emitting or super-emitting sources or possible sources of error introduced by flawed measuring equipment. In addition, the use of a Global Warming Potential multiplier of 25 for methane, which is based on a 100-year time horizon, rather than 86 for a 20-year time horizon, has come under sustained criticism given the urgency of the climate crisis.^{991, 992}

- April 7, 2016 – Since 2009, corresponding to the advent of the U.S. shale gas boom, North American ethane emissions have increased by 5 percent per year. This trend represents a reversal of a previous multi-decade decline (mid-1980s until the end of the 2000s) in the abundance of atmospheric ethane that had been attributed to the reduction of fugitive emissions from fossil fuel sources. These are the findings of an international research team, which analyzed remote sensing data gathered by the Network for the Detection of Atmospheric Composition Change at globally distributed ground-based sites. Ethane is a volatile organic compound (VOC) that readily reacts with nitrogen oxides in the presence of sunlight to create ground-level ozone (smog). Also a potent greenhouse gas, ethane is co-released along with methane from drilling and fracking sites. The source of two-thirds of the ethane in Earth’s atmosphere is leakage from natural gas wells and pipelines. Because ethane is co-emitted with methane and can serve as a marker for it, this documentation of a sharp, recent uptick in atmospheric ethane is part of a larger body of evidence suggesting that U.S. drilling and fracking operations are

driving up global methane levels.⁹⁹³ (See also entry dated June 13, 2016 in Air Pollution section].)

- April 5, 2016 – A research team using infrared cameras and helicopters demonstrated that between 1 and 14 percent of oil and gas well pads surveyed were high emitters of hydrocarbons and VOCs, with the greatest number observed in oil producing areas and in areas with horizontal drilling.⁹⁹⁴ While some emissions were intentional or part of routine maintenance operations, fugitive, unplanned releases (as from malfunctioning equipment) were also common, as were combustion emissions (as from flares and compressor engine exhaust). Tank vents and hatches were the origin of the vast majority (>90 percent) of detected large emission sources, deeply undercutting the assumption in the EPA’s Oil & Gas Emission Estimation Tool of 100 percent capture efficiency by tank control systems. While emissions tended to be higher during the first few months of well production, predicting which wells or other sources would become high emitters was not possible. The lead author, speaking to *InsideClimate News*, concluded that the work “really demonstrates the importance of things like continuous detection or frequent monitoring to find these high emission sites.”⁹⁹⁵
- March 10, 2016 – Attempting to explain a methane plateau between 1999 and 2006 within otherwise almost continuously increasing levels of atmospheric methane since the dawn of the industrial revolution, an international team of atmospheric scientists reconstructed the global history of methane and used isotopic carbon fingerprinting to parse the sources of its emission. Thermogenic emissions were assumed to result from fossil-fuel sources, while biogenic sources were assumed to arise from wetlands and agricultural operations. Based on a geographic distribution of methane revealed by remote sensing, the authors concluded that agricultural emissions, especially increases in livestock inventories and rice cultivation, were the most likely drivers of observed global methane increases from 2006 to 2014.⁹⁹⁶ These results stand in contrast to other contemporaneous and recent studies that have supplied evidence for the role of oil and gas extraction in the recent upsurge in atmospheric methane.⁹⁹⁷ (See entry for February 16, 2016 below.)

- February 16, 2016 – A Harvard-led team used both satellite retrievals and surface observations to estimate that methane emissions in the United States increased by more than 30 percent over the past twelve years. These findings, which contradict the 10 percent decline reported by the EPA, suggest that the United States could be responsible for 30-60 percent of the recent global spike in atmospheric methane.^{998, 999} Since 2015, research on atmospheric methane has frequently relied on an “inverse method” to optimize emission estimates by combining “bottom-up” and “top-down” data, yet data from different sources have not yielded consistent estimates of methane emissions and levels. Three major sources (Wecht et al. [2014], Miller et al. [2013], and Turner et al. [2015]) all found maximum emissions in the South Central United States, with spatial overlaps that made separating livestock sources from oil and gas sources difficult. Taking into account the time period investigated by differing studies reveals an increasing trend in methane emissions, with an increase of 38 percent from 2004 to 2011, a period of greatly increasing drilling activity. This trend is confirmed by analyzing temporal trends in satellite data. While this account still differs from the EPA’s inventory in 2014 showing a 3 percent decrease in oil and gas emissions over that same time period, the EPA’s data presumed better control of measured leaks, which may not correlate with better control of overall emissions.
- January 29, 2016 – Working in the Marcellus Shale Basin, a Carnegie Mellon research team compared methane emissions from older conventional gas wells (those that were vertically drilled) and newer, unconventional gas wells (those that combined fracking with horizontal drilling). Measured by facility, the mean emission rate for unconventional wells was 23 times higher than that of conventional wells. This difference, in part, was attributed to the larger size of unconventional well pads, which, typically, have multiple wells per pad, more ancillary equipment, and produce more gas. When corrected for production, the conventional wells leaked more—that is to say, they lost a comparably larger fraction of methane per unit of production—likely due to “unresolved equipment maintenance issues.” All together, the authors concluded, these new emissions data show that the recently instituted Pennsylvania Department of Environmental Protection’s (PA DEP) methane emissions inventory substantially underestimates facility-level methane emissions. Five unconventional well sites included in this study leaked 10-37 times more methane than estimated in the state inventory.¹⁰⁰⁰
- January 25, 2016 – Cornell University scientists introduced an innovative methodology for assessing potential climate impacts of alternative choices and used it to demonstrate that emissions of the two most important greenhouse gases (carbon dioxide and methane), calculated as time-integrated radiative forcing, are lower with heat pump water heaters than any other means of heating water. Further, their calculations showed that

heat pump water heaters powered by coal-generated electricity achieve greater net climatic benefit than heaters powered by natural gas, while even greater benefits may be achieved by combining heat pump water heaters with electricity generated by renewable sources. The authors proposed and justified a methane emission rate of 3.8 percent for conventional shale gas, which is therefore offered as a lower bound for future, tightly controlled methane emissions from unconventional gas activities. The authors also made their web-based tool for evaluating the greenhouse gas footprint of reference and alternative technologies and its source code available to the public (at <http://www.eeb.cornell.edu/howarth/methane/tool.htm>).¹⁰⁰¹

- December 22, 2015 – To reconcile troubling divergences in published estimates of methane emissions, in which “top-down” estimates, based on atmospheric or satellite sampling, often exceed “bottom-up” estimates, based on ground-level sampling or individual source reports, researchers used a combination of repeated mass balance measurements plus ethane fingerprinting to improve top-down estimates and incorporated a more complete and detailed count of facilities to improve bottom-up estimates.¹⁰⁰² The results, as demonstrated in the Barnett Shale oil and gas-producing region of Texas, revealed a convergence of estimates to within 10 percent for fossil methane and 0.1 percent for total methane, with predicted methane emissions 90 percent larger than those estimated by the EPA’s Greenhouse Gas Inventory. Exclusion of additional problematic studies might have resulted in even greater convergence and higher estimates.¹⁰⁰³ The agreement between top-down and bottom-up estimates demonstrates that well-designed surveys using either approach can be useful, with spatially resolved bottom-up estimates pointing toward production sites as the source of 53 percent of emissions, compressor stations 31 percent of emissions, and processing plants 13 percent of emissions. The Barnett shale emission rate of 1.5 percent calculated in this study is low enough (less than 3 percent) to suggest that gas fired electricity production in this region causes less climate forcing than coal-fired electricity, but it is high enough (greater than 1 percent) to argue against the conversion of diesel powered freight trucks to compressed natural gas. Gas production practices and heavier activity in other basins may lead to higher emission rates, as may the storage and long-distance or very long-distance transmission of natural gas.
- December 22, 2015 – Writing for *Environment & Energy Publishing*, journalist Gayathri Valdyanathan reported on efforts by climate scientists to convince the United Nations to stop expressing the heat-trapping potential of methane over a 100-year time frame and instead use a twenty-year time frame when generating global warming potential, the conversion factor that allows policymakers to compare methane’s ability to trap heat with that of carbon dioxide. Methane is a far more potent heat-trapping gas than is carbon

dioxide, but it is also shorter lived. By convention, policymakers have used a 100-year time frame when calculating global warming potentials. However, there is no scientific reason to do so, and many scientific critics argue that choosing this time scale veils the true climate impacts of natural gas and “makes the gas appear more benign than it is.”¹⁰⁰⁴

- November 25, 2015 – Using reports from countries and companies with proved reserves of recoverable oil, natural gas, and coal, an analysis published in *Global Environmental Change* shows that full production of these resources would use up 160 percent of the world’s estimated remaining carbon budget (designed to restrict anthropogenic climate change to equal to or less than 2° C). While 76 percent of reserves are owned by states or state entities, the relatively smaller amount of reserves owned by investors poses the greater immediate threat, since those companies are more likely poised to produce, refine, and deliver fossil fuels to global markets in the near term. However, exploitation of existing proved reserves controlled by the private sector alone does not lead to warming above the 2° limit, if it is not accompanied by exploration for and development of new reserves. Future considerations of fossil fuel use should focus not only on reducing private sector contributions but also on reducing contributions from countries that have historically dominated or currently dominate emissions, and especially nation-states with large undeveloped reserves.¹⁰⁰⁵
- November 9, 2015 – Including data available through 2014, the World Meteorological Organization (WMO) reported that globally averaged levels of carbon dioxide, methane, and nitrous oxide reached new highs in 2014, with values, respectively, “143%, 254% and 121% of pre-industrial (1750) levels.”^{1006, 1007} While the atmospheric increase in carbon dioxide has slowed, methane and nitrous oxide levels continue to increase. Measurements from the WMO’s Global Watch Programme point to wetlands in the tropics and anthropogenic sources at mid-latitudes of the northern hemisphere as the sources of increased methane over the past decade.
- October 8, 2015 – As a foundation for policy recommendations, Cornell University biogeochemist Robert Howarth summarized and analyzed the evidence documenting the magnitude of methane emissions related to oil and gas development in the United States since 2007. With estimated emission rates ranging from 3.8-12 percent, the high radiative forcing of methane over a twenty-year period prevents natural gas from serving as a bridge fuel. Instead of further investments in natural gas, Howarth proposes a rapid transition to electric powered vehicles for transportation, high-efficiency heat pumps for space and water heating, and imposition of a methane tax that is roughly 86 times higher

than currently proposed carbon taxes, which typically address only carbon dioxide.¹⁰⁰⁸ Howarth also noted that the EPA “has seriously underestimated the importance of methane emissions in general—and from shale gas in particular.”¹⁰⁰⁹

- August 4, 2015 – A developer of high flow sampling technology determined that a commonly used instrument to quantify methane leakage has unreliable sensors and malfunctions in ways that vastly underreport emissions by factors of three to five. More than 40 percent of the compiled national methane inventory may be affected by this measurement failure, according to the author of this study.¹⁰¹⁰ The implications of this discovery for our understanding of system-wide methane leakage rates from drilling and fracking operations are not known, but they do call into question the results of at least one major study of methane emissions that relied on this device for collecting data. This is the second of two studies that finds that the primary tool approved by the EPA for measuring and reporting emissions of methane fails to function properly when used as directed by the manufacturer. (See also entry below dated March 24, 2015.)
- July 21, 2015 – An international team of researchers investigated the claim that the fracking boom, which has dramatically increased supplies of natural gas in the United States, is the main driver of the modest decline in carbon dioxide emissions since 2007. Conventional wisdom, as expressed by the Third National Climate Assessment of the U.S. Global Change Research Program, attributes the drop in emissions to a shift away from carbon dioxide-intensive coal and toward natural gas in power plants. But this team analyzed the sources of change in carbon dioxide emissions and, using a tool called input-output structural decomposition analysis, documented that the economic downturn, not fuel switching in the power sector, was the explanation for declining carbon dioxide emissions since 2007. The single biggest impact on U.S. emissions was changes in the volume of goods and services consumed. Between 2007 and 2013, driven by a huge drop in the volume of capital investment, emissions associated with capital formation decreased by almost 25 percent. During the same period, emissions related to household consumption decreased by 11 percent.¹⁰¹¹
- July 7, 2015 – A scientific opinion piece by Environmental Defense Fund researchers involved in a group of 11 studies on methane emissions in Texas’ Barnett Shale provided an overview and orientation to new research that either measured or estimated methane emissions from oil and gas operations. Research from both top-down estimates (based on measuring atmospheric methane or related compounds at regional or larger scales) and bottom-up measurements (made directly from components or at ground level near

studied sites) demonstrated that methane emissions from oil and gas operations in the Barnett Shale region exceeded the emissions expected from the EPA's greenhouse gas inventory, which relies on industry self-reporting and excludes many compressor stations. The new research detailed the importance of addressing high-emitting landfills and natural gas facilities ("super-emitters") and malfunctioning equipment in efforts to control ongoing methane emissions.¹⁰¹²

- May 28, 2015 – A comprehensive working paper from the New Climate Economy initiative of the Global Commission on the Economy and Climate at Stockholm Environment Institute found that the experience in the United States of substituting natural gas for oil was unlikely to be replicated around the globe and probably will not provide climate benefits unless coupled with strict controls on methane leakage, limits on total energy use, and policies to prevent the displacement of non-fossil fuel energy by methane. Citing multiple studies of the net climate impact of "more abundant, cheaper natural gas supplies," the Commission concluded that "both globally and for the United States, the increase in emissions from the scale effect [from increased energy consumption boosted by cheap natural gas and loss of potentially more expensive lower carbon approaches] fully offsets the emission benefits from the substitution effect, net of methane leakage."^{1013, 1014}
- March 24, 2015 – A University of Cincinnati researcher and independent engineers documented that the Bacharach Hi-Flow Sampler (BHFS)—one of the only tools approved by the EPA for measuring and reporting emissions of methane from natural gas transmission, storage, and processing facilities—failed to function properly when used as indicated by the manufacturer. The BHFS, unless recalibrated daily and running revised software (or taking measurements in a nearly pure methane environment, which is exceedingly rare in the field), misreported high levels of natural gas by as much as an order of magnitude lower than actual concentration. A reanalysis of 2011 results from the City of Fort Worth Air Quality Study revealed at least seven instances for which the BHFS indicated sample concentrations at or below 5 percent when more reliable canister methane readings indicated concentrations that ranged from 6.1 percent to 90.4 percent. Inaccurate measurements like these can contribute to the discrepancy between "top-down" and "bottom-up" measurements of methane, with ground-level measurements from the BHFS potentially producing reports of falsely low emissions.¹⁰¹⁵ This study was followed by another that further documented malfunctions in the BHFS device and called

into question the results of a landmark 2013 survey of methane emissions at 190 drilling and fracking sites across the United States. That 2013 survey, from the University of Texas, relied on the BHFS device for collecting data and found very low leakage rates.¹⁰¹⁶ (See also entry above dated August 4, 2015.)

- March 20, 2015 – A team led by Bruno Franco from the University of Liege in Belgium discovered an abrupt uptick in ethane levels at a mountaintop station in the Swiss Alps that is far removed from local pollution sources.¹⁰¹⁷ In a later comment about this discovery, Franco said, “Since 2009, we observed increases of 5% per year here—it was completely unexpected.”¹⁰¹⁸ The team attributed the trend reversal to the natural gas boom in North America. Ethane is released together with methane from drilling and fracking operations and serves as a proxy for it. (See also the entry above for April 7, 2016.)
- March 9, 2015 – With specialized equipment in a mobile van, University of Colorado, NOAA, Environmental Defense Fund, and independent researchers continuously measured methane and ethane from public roads at sites downwind of potential emission sources, such as natural gas production wellheads, processing plants, and compressor stations. The sampling method and modeling allowed capture of multiple “accidental” plumes, acquired during long drives across the study region between planned measurements near large facilities. Sampling was not random but documented a large number of facilities with low methane emission rates (equal to or less than 10 kg/hr), with a smaller yet important number of facilities showing much higher emissions. Although the largest measured emission in this study (1,360 kg/hr) corresponded to approximately \$1.2 million in lost revenue per year, the authors noted that, in this industry, the “leak fraction” or “proportional loss” levels they documented would generally translate into only a small proportion of lost revenue, probably not sufficient to prompt strong energy-sector self-regulation.¹⁰¹⁹
- March 1, 2015 – Using a simulation model, the Federal Ministry for the Environment, Nature Conservation, Building and Nuclear Safety, writing for Germany’s Federal Environmental Agency, found that shale gas was not a cheap option to reduce global greenhouse gas emissions. Multiple comparison simulations found that shale gas availability, especially in the short-term, tends to lead to higher emissions due to lower energy prices inducing higher use. The net result is higher costs to achieve compliance

with climate targets. In this model, shale gas was also found to compete in an unhelpful way with renewable energy sources, resulting in reduced use of renewable energy sources and reduced investment in energy efficiency measures.¹⁰²⁰

- January 8, 2015 – Using a single integrated modeling program that incorporates detailed estimates of the world’s reserves of oil, gas, and coal and is consistent with a wide variety of prior modeling approaches, University College London researchers demonstrated that, around the world, “a third of oil reserves, half of gas reserves and over 80 per cent of current coal reserves should remain unused from 2010 to 2050” in order to meet a target of less than or equal to a 2 degree Celsius rise in global temperature. In addition, “development of resources in the Arctic and any increase in unconventional oil production are incommensurate with efforts to limit average global warming” below the 2 degree threshold. Calling for a “stark transformation” of our understanding of fossil fuel availability, the authors noted that, in a climate-constrained world, fears of scarcity of fossil fuels must be superseded by a commitment to preventing overuse of existing resources and reserves.¹⁰²¹
- November 26, 2014 – Stanford University and independent researchers compared coal and natural gas for power generation and concluded that the question of “whether natural gas plants are better than coal plants cannot be answered in the general case.” During the period of plant operation, “natural gas plants can produce greater near-term warming than coal plants, with the same power output.” They found that over time, natural gas plants can produce some reduction in near-term warming, but only if life cycle methane leakage rates are low and power plant efficiency is high. Relative to coal, there is the potential that “deployment of natural gas power plants could both produce excess near-term warming (if methane leakage rates are high) and produce excess long-term warming (if the deployment of natural gas plants today delays the transition to near-zero emission technologies).”¹⁰²²
- October 23, 2014 – Adding to the debate about natural gas and climate change, a multi-center, international research team used a sophisticated, integrated approach to the global energy-economy-climate systems question and found no climate benefit to natural gas over other fossil fuels. As summarized by the editor of *Nature*,

The development of hydraulic fracturing technologies has led to rapid growth in the use of natural gas as an energy source. Some evidence has suggested that this growing adoption of natural gas might lead a reduced greenhouse gas burden and consequent mitigation of climate change. This collaboration between five energy–

climate modelling teams show that instead—under a scenario of abundant natural gas availability—increased consumption will have little or no impact on climate change.” The authors concluded, “although market penetration of globally abundant gas may substantially change the future energy system, it is not necessarily an effective substitute for climate change mitigation policy.”¹⁰²³

- October 6, 2014 – Utilizing satellite data for the Bakken and Eagle Ford formations, scientists from Germany, the United Kingdom, and the University of Maryland confirmed that higher “top-down” estimates of fugitive methane leaks from oil and gas fields (which are obtained via tall tower flask samples, aircraft measurements, and road surveys) are more accurate than lower “bottom-up” estimates (which are obtained by summing emissions from different types of known sources at sites provided by participating utility companies). According to “bottom-up” estimates, the average U.S. leakage rate ranges from 1.2-2.0 percent. But satellite data show much higher leakage rates: 10.1 percent (\pm 7.3 percent) and 9.1 percent (\pm 6.2 percent), for the Bakken and Eagle Ford formations, respectively. These higher estimates indicate that current inventories likely underestimate fugitive emissions and call into question any immediate climate benefit from switching from coal to natural gas. Similar results were seen for the Marcellus shale region, but as a result of technical and geographical limitations, the authors declined to quantify their results, pending future studies with enhanced equipment.¹⁰²⁴
- September 24, 2014 – According to a paper published by scientists from the University of California and Stanford University, “... without strong limits on [greenhouse gas] emissions or policies that explicitly encourage renewable electricity, abundant natural gas may actually slow the process of decarbonization, primarily by delaying deployment of renewable energy technologies.” The study builds on previous research by examining natural gas in a range of supply curves, with a tested economic model, and across three different types and levels of climate policy. Researchers found that abundant natural gas, even with low rates of methane leakage, does little to reduce—and may increase—greenhouse gases. They conclude that delaying deployment of renewable energy technologies “may actually exacerbate the climate change problem in the long term.”¹⁰²⁵
- September 2, 2014 – Analyzing the level of greenhouse gas emissions attributable to electricity from natural-gas-fired power plants and coal-fired power plants, economist Chris Busch and physicist Eric Gimon conclude that, over short time frames and at high rates of leakage, natural gas offers little benefit compared to coal and could exacerbate global warming. Although Busch and Gimon acknowledge that natural gas offers some reductions in greenhouse gas emissions over longer time frames, they point out that such

reductions are not large enough for natural gas to play an expanded role in efforts to manage emissions. They conclude that under the best of circumstances, natural gas-fired electric power offers a modest benefit toward abating climate change, while if poorly developed (i.e., with extensive methane leaks, estimated by these authors to be on the order of 4 percent or higher), or if used to displace energy efficiency or renewable energy, natural gas could seriously contribute to increased greenhouse gas emissions.¹⁰²⁶

- August 5, 2014 – Reporting in *Scientific American*, the science news organization Climate Central outlined the natural gas-related factors that threaten any ability to achieve climate goals through the proposed Clean Power Plan. “No one has any idea how much methane is leaking from our sprawling and growing natural gas system. This is a major problem, because without a precise understanding of the leak rate natural gas could actually make climate change worse.” Referring to an interactive Climate Central tool that runs various methane leakage scenarios, the article notes that, even given modest leak rates and an aggressive transition, “we could still end up with little or no climate benefits by 2030 after an enormous financial and political investment in natural gas.”¹⁰²⁷
- July 25, 2014 –EPA’s Office of Inspector General reports that the agency “has placed little focus and attention on reducing methane emissions from pipelines in the natural gas distribution sector.” According to this report, the EPA acknowledged in 2012 that leaks from natural gas pipelines “accounted for more than 13 million metric tons of carbon dioxide equivalent emissions,” are almost 100 percent methane, and represent more than 10 percent of total methane emissions from natural gas systems in the United States. Nevertheless, as report went on to note, the EPA does not have the partnerships in place to begin controlling methane leaks, such as with the Pipeline and Hazardous Materials Safety Administration, nor has it conducted a comprehensive analysis of emissions factors, relying instead on a 1996 study with a “high level of uncertainty.”¹⁰²⁸
- May 15, 2014 – A recent review of existing data on life cycle emissions of methane from natural gas systems concluded that, as a strategy for addressing climate change, natural gas is a “bridge to nowhere.” The review found that, over a 20-year time frame, natural gas is as bad as or worse than coal and oil as a driver of climate change.¹⁰²⁹ Referencing this review and other recent studies, *Bloomberg Business News* reported that the EPA has underestimated the impact of methane leakage resulting from the production, transmission, and distribution of natural gas and is using outdated estimates of methane’s

potency compared to more recent estimates from the Intergovernmental Panel on Climate Change (IPCC).¹⁰³⁰

- April 25, 2014 – A reassessment of the heat-trapping potential of greenhouse gases revealed that current methods of accounting underestimate the climate-damaging impact of methane pollution from all sources, including drilling and fracking operations.¹⁰³¹
- April 14, 2014 – A study from researchers at Purdue University, NOAA, Cornell University, University of Colorado at Boulder, and Pennsylvania State University, published in *Proceedings of the National Academy of Sciences* found very high levels of methane emissions above many wells being drilled at fracking sites in Pennsylvania. Levels were 100-1,000 times above the estimates of federal regulators, who have always assumed very low methane emissions as wells are drilled.^{1032, 1033}
- February 26, 2014 – The United Nations’ top environmental official, Achim Steiner, argued that the shale gas rush is “a liability” in efforts to slow climate change and that a switch from coal to natural gas is delaying critical energy transition to renewables.¹⁰³⁴
- February 13, 2014 – A major study in *Science* by Stanford University, Massachusetts Institute of Technology, and the U.S. Department of Energy found that methane leaks negate any climate benefits of natural gas as a fuel for vehicles, and that the EPA is significantly underestimating methane in the atmosphere.¹⁰³⁵ Lead author Adam R. Brandt told the *New York Times*, “Switching from diesel to natural gas, that’s not a good policy from a climate perspective.”¹⁰³⁶ This study also concluded that the national methane leakage rate is likely between 3.6 and 7.2 percent of production.

- January 15, 2014 – As reported by the *Guardian*, a new study by BP concluded that shale gas “...will not cause a decline in greenhouse gases” and will do little to cut carbon emissions.¹⁰³⁷
- December 30, 2013 – An analysis of fracking-related truck transportation in the Susquehanna River Basin in Pennsylvania found that greenhouse gas emissions from frack water and waste hauling operations were 70-157 metric tons of CO₂ equivalent per gas well.¹⁰³⁸
- November 11, 2013 – In a letter to California Governor Jerry Brown, twenty of the nation’s top climate scientists warned that pro-fracking policies will worsen climate disruption and harm California’s efforts to be a leader in reducing greenhouse gas emissions. The letter called on Governor Brown to place a moratorium on fracking.¹⁰³⁹ On November 21, 2013, a group of Governor Brown’s former policy and campaign advisors made a similar request in light of concerns about the effects of fracking on climate change and water pollution.¹⁰⁴⁰
- October 18, 2013 – A team of researchers from multiple institutions including Harvard, the University of Michigan, and NOAA reported that methane emissions due to drilling activities in the south-central U.S. may be almost five times greater than reported by the world’s most comprehensive methane inventory. “These results cast doubt on the US EPA’s recent decision to downscale its estimate of national natural gas emissions by 25-30 percent,” the authors wrote.¹⁰⁴¹ As the *New York Times* reported, “The analysis also said that methane discharges in Texas and Oklahoma, where oil and gas production was concentrated at the time, were 2.7 times greater than conventional estimates. Emissions from oil and gas activity alone could be five times greater than the prevailing estimate.”¹⁰⁴²
- October 18, 2013 – A major study spearheaded by Stanford University’s Energy Modeling Forum concluded that fracking and the shale gas revolution will have no long-

term climate benefit. The study brought together a working group of about 50 experts and advisors from companies, government agencies, and universities, and modeling teams from 14 organizations. The study also found that build-out of infrastructure for fracking and natural gas will discourage efforts to conserve energy and boost efficiency. The study did not examine methane leaks in order to weigh in on the short-term climate impacts of natural gas.¹⁰⁴³

- October 11, 2013 – As reported in the *Guardian*, key climate scientists argued that the growth in fracking across the United States is hurting the United States’ credibility on climate change.¹⁰⁴⁴
- October 2, 2013 – Updated measurements from the IPCC determined that methane is even worse for the climate than previously thought. The IPCC determined that methane is 34 times more potent as a greenhouse gas in the atmosphere than CO₂ over a 100-year timeframe, and 86 times more potent over a 20-year timeframe.¹⁰⁴⁵
- September 27, 2013 – The IPCC formally embraced an upper limit on greenhouse gases for the first time, warning that the world will exceed those levels and face irreversible climatic changes in a matter of decades unless steps are taken soon to reduce emissions. The IPCC reported that humanity faces a “carbon budget”—a limit on the amount of greenhouse gases that can be produced by industrial activity before irreversible, damaging consequences—of burning about a trillion metric tons of carbon. The world is on track to hit that by around 2040 at the current rate of energy consumption.¹⁰⁴⁶
- August 12, 2013 – A *New Scientist* review of the science on fracking and global warming concluded that fracking could accelerate climate change rather than slow it.¹⁰⁴⁷
- May 28, 2013 – A research team led by Jeff Peischl, an associate scientist at NOAA and the Cooperative Institute for Research in Environmental Sciences, estimated that methane leakage from Los Angeles-area oil and gas operations was about 17 percent.^{1048, 1049}

- May 2013 – A group of scientists and journalists studying climate change, led by energy systems analyst Eric Larson of Princeton University and the news organization Climate Central, reported that the often-purported 50 percent climate advantage of natural gas over coal is unlikely to be achieved over the next three to four decades given methane leaks and other factors.¹⁰⁵⁰ The 50 percent claim is based on the fact that natural gas produces half as much carbon dioxide when burned than coal, but it ignores the significant greenhouse gas impacts of methane leakage that occurs throughout the life cycle of natural gas production, transmission, and distribution.
- January 2, 2013 – A NOAA study found methane emissions from oil and gas fields in Utah to be as high as nine percent of production. These levels are considered extremely damaging to the climate.¹⁰⁵¹
- November 2012 – A review by the United Nations Environment Programme found that emissions from fracking, as well as other unconventional natural gas extraction methods, could increase global warming in the short-term and be comparable to coal over a 100-year timeframe.¹⁰⁵²
- November 2012 – The International Energy Agency (IEA) found that a large natural gas boom—even with improvements in place to reduce leakage—would eventually lead to greenhouse gas concentrations of 650 parts per million and a global temperature rise of 3.5 degrees Celsius, far exceeding the 2 degree Celsius limit which is critical to avoid the most severe effects of climate change.¹⁰⁵³
- May 29, 2012 – The *Guardian* summarized a special report on natural gas by the IEA: “A ‘golden age of gas’ spurred by a tripling of shale gas from fracking and other sources of unconventional gas by 2035 will stop renewable energy in its tracks if governments do not take action.”¹⁰⁵⁴
- February 2012 – A study published in *Environmental Research Letters* found that the carbon dioxide emitted from the burning of natural gas—even neglecting the impacts of methane leakage—contributes significantly to greenhouse gas emissions that are driving climate change.¹⁰⁵⁵

- February 7, 2012 – A NOAA study of Colorado gas fields measured methane emissions of about four percent, a significant percentage that could be very damaging to the climate.¹⁰⁵⁶
- December 29, 2011 – As reported by the *New York Times*, levels of methane in the atmosphere have been steadily rising since 2007—coinciding with the onset of the fracking boom and posing a serious threat to the Earth’s climate.¹⁰⁵⁷
- October 2011 – A study from the National Center for Atmospheric Research concluded that substituting the use of natural gas for coal will increase, rather than decrease, the rate of global warming for many decades.¹⁰⁵⁸
- July 6, 2011 – According to the U.S. Energy Information Administration and other research, significant amounts of methane are leaking from aging gas pipelines and infrastructure.¹⁰⁵⁹
- April 2011 – A comprehensive analysis of the greenhouse gas footprint of natural gas from shale formations found that between 3.6 percent to 7.9 percent of the methane from natural gas production wells escapes into the atmosphere, rather than being combusted, thereby undermining any climate benefits of gas over coal as a source of energy.^{1060, 1061}

Threats from fracking infrastructure

The infrastructure for drilling and fracking operations is complex, widespread, and poses its own risks to public health and the climate. Beginning where silica sand is mined and processed and ending where gas is burned or liquefied for export, infrastructure includes pipelines, compressor stations, dehydrators, processing plants, flare stacks, gas-fired power plants, and storage depots through which oil or gas is moved, filtered, pressurized, warehoused, refined, and vented. It also includes injection wells and recycling facilities that dispose and treat the prodigious amounts of liquid waste that fracking generates. Air pollution is produced at every stage of the process. [Note: harm from flare stacks is included in Air Pollution and is not taken up in the sub-sections that follow.]

Sand mining and processing

In the Upper Midwest, the boom in silica sand mining threatens both air and water quality. It has transformed rural areas into industrialized zones and introduced complex public health risks that are not well understood. Silica dust is a well-known cause of both lung cancer and silicosis. Precise exposures to downwind communities remain uncertain. Until recently, the center of frack sand mining was western Wisconsin. However, sand mines in the Permian Basin of west Texas now provide one quarter of the total U.S. supply of frack sand. Texas sand is considered inferior to Wisconsin sand, which is crush-resistant and ideally shaped to prop open fractures to allow oil and gas to flow up the borehole. However, Texas sand is up to 50 percent cheaper as it does not incur the cost of rail transport to reach the booming Permian Basin oil wells.

- March 7, 2019 – The Minnesota Supreme Court announced that it would hear oral arguments on the legality of Winona County’s ban on the mining of silica sand for use in fracking operations. A Winona County judge, as well as a Minnesota Court of Appeals, sided against Minnesota Sands, LLC and ruled in favor of the county legislature.¹⁰⁶² The ban prohibits mining sand for industrial purposes but allows mining for construction purposes. The county has argued that it is within its rights to protect the health of its citizens. Its original ordinance, passed on November 22, 2016, was the first countywide ban in the nation on the extraction of silica sand for use in drilling and fracking operations. It became the subject of a lawsuit by Minnesota Sands on the grounds that the ordinance violates the federal Commerce Clause of the U.S. Constitution.^{1063, 1064}

- December 27, 2018 – Wisconsin’s frack sand mining industry had a volatile year in 2018. Mines that had closed in 2016 due to market downturns reopened on news of increased drilling activity. However, later in the year, the price for sand dropped dramatically as sand mines opened in Texas to serve fracking operations in the nearby Permian Basin. Wisconsin sand companies then closed mines again, with one company laying off 37 employees.¹⁰⁶⁵
- July 17, 2018 – As part of an industry-funded study, a research team retrospectively assessed the silica dust exposure among workers in the industrial sand industry, which includes sand used for fracking. Workers who went on to develop silicosis had significantly more exposure to silica dust than those who did not. Results showed decreases in exposure throughout the industry over time, driven in part by the establishment of workplace regulations in the 1970s that helped accelerate silica dust control programs. Adjustment for use of respiratory protection showed only modest reductions in estimated exposures.¹⁰⁶⁶
- May 11, 2018 – The dunes sagebrush lizard in western Texas is imperiled because of booming demand for frack sand. “It’s really a new threat and it just sort of came in all at once and really has the potential to wipe out a lot of lizard habitat, if not controlled,” said a petition to the U.S. Fish and Wildlife Service that urged the agency to add the dunes sagebrush lizard to the endangered species list.¹⁰⁶⁷ Sand mines in the Permian Basin of west Texas now provide one quarter of the total U.S. supply of frack sand. Texas sand is up to 50 percent cheaper than Wisconsin sand as it does not incur the cost of rail transport to reach the booming Permian Basin oil wells, although it is considered inferior to Wisconsin sand, which is crush-resistant and ideally shaped to prop open fractures to allow oil and gas to flow up the borehole.¹⁰⁶⁸
- August 7, 2017 – A University of Iowa team evaluated the impact of frack sand mining and processing on the concentration of particulate matter in the air of surrounding communities. Sampling in 17 homes located within 800 meters from sand mining activities, the team found that, overall, particulate matter and silica concentrations were lower than regulations and guidelines established to prevent silicosis but spiked when winds blew over the facility. They concluded that particulate matter levels from fracking sand mining and processing were “unlikely to cause chronic adverse health conditions.” Sampling for this study, which took place in 2014, did not consider the impact of living

near multiple adjacent frack sand operations. The industry in western Wisconsin has expanded considerably since that time.¹⁰⁶⁹

- November 25, 2017 – In Minnesota, a district judge upheld Winona County’s ban on the mining, processing, and loading of frack sand. In her decision, the judge referenced public health and safety threats, fragility of the water quality in the area, and evidence for harm from sand mines in other areas. Winona is the first county in the United States to pass a countywide ban on frack sand extraction. Efforts to replicate the ban are now ongoing in neighboring counties.^{1070, 1071}
- July 5, 2016 – The Wisconsin Department of Natural Resources (DNR) released a *Strategic Analysis for Public Review* of the state’s industrial sand mining industry that downplayed environmental health effects from air pollution. There are 128 industrial sand mine facilities in Wisconsin, including the mines themselves and processing and rail loading facilities. The DNR identified airborne particulate matter as a primary concern for industrial sand mining facilities and said that air quality monitors in western Wisconsin have not detected a problem.¹⁰⁷² Researchers, organizations, and the native community involved in monitoring impacts of the frack sand industry challenged these findings, pointing to lack of data collection on the most dangerous kind of particulate matter called PM2.5, which represents fine particles that are less than 2.5 microns in width. These critics noted that the U.S. Environmental Protection Agency (EPA) had previously expressed concerns about the DNR’s approach to regulating PM2.5.¹⁰⁷³ Regarding groundwater, the report described elevated levels of several metals in wastewater holding ponds at the sand mines, presenting a risk to groundwater quality.
- March 25, 2016 – The Occupational Safety and Health Administration (OSHA) amended its existing standards for occupational exposure to respirable crystalline silica, “having determined that employees exposed to respirable crystalline silica at the previous permissible exposure limits face a significant risk of material impairment to their health.”¹⁰⁷⁴ Key provisions include the reduction of the permissible exposure limit to 50 micrograms per cubic meter of air, averaged over an 8-hour shift. The standards cover many industries with some having two years to comply; the hydraulic fracturing industry

is allowed an additional five-year extension for engineering controls, until June 23, 2021.¹⁰⁷⁵ The *New York Times* reported that safety experts have advocated for a tightening of silica exposure standards for the past forty years but that “progress was stymied for decades by resistance from affected companies and regulatory inaction.” The article reported that many oil and gas companies in particular were not meeting the current silica exposure standard. The new rules, when fully in effect, are estimated to save 600 lives and prevent 900 new cases of silicosis per year.¹⁰⁷⁶

- March 1, 2016 – University of Wisconsin anthropologist Thomas Pearson conducted in-depth interviews examining the impact of frack sand mining on sense of community, quality of life, and place in nearby residents. His findings indicated that the sudden influx of this heavy extractive industry has eroded residents’ sense of place and belonging and that these experiences are rarely taken into account by policymakers. Residents report “significant anxiety and stress from truck traffic, noise, light pollution, and uncertainty about environmental health impacts,” and distress caused by drastic changes to long-familiar landscapes over which they have no control. Pearson concluded that policymakers should pay closer attention to the uneven distribution of benefits and costs and “recognize that the costs go beyond quantifiable economic or environmental impacts.”¹⁰⁷⁷
- January 29, 2016 – The Institute for Wisconsin’s Health, Inc. released its Health Impact Assessment (HIA) on frack sand mining operations in western Wisconsin, prepared with the participation of 15 local and tribal health departments. According to the report, the HIA was a collaborative effort. The scope of the report was limited to the potential for community-level health effects of industrial sand mining in western Wisconsin. Regarding air quality, the report concluded that health effects from the impact of industrial sand mining on community-level air quality related to particulate matter are unlikely, and that it was also unlikely that community members would be exposed to respirable crystalline silica from industrial sand mining as currently regulated. Regarding water quality, the report concluded that contamination is possible; however, health effects were unlikely. Quality of life effects were likely, but variable.¹⁰⁷⁸ Though it was a “Level 1 Partner” for the report, the Ho-Chunk Nation responded to the HIA with criticism, writing, “we are disappointed with the conclusions drawn in the report, particularly in the section on air quality impacts, and we believe a more robust assessment of the air quality impacts is required before such conclusions can be drawn.” They wrote that the HIA failed to provide an accurate and complete analysis of the health threats posed by this

industry because of the limited scope, and “minimal discussion about fine particulate matter (or PM_{2.5}), which likely presents the biggest threat from industrial sand mining operations.¹⁰⁷⁹ As reported by Rochester, Minnesota’s *Post-Bulletin*, Crispin Pierce, director of University of Wisconsin-Eau Claire’s environmental public health program, “believes the study ignored important air quality data collected by university students at sand mining sites at Bloomer, New Auburn and Augusta during the past 18 months,” which he described as “the only work that looked at these fine particles.”¹⁰⁸⁰

- November 6, 2015 – According to findings from a pilot study led by Crispin Pierce (see entry above), levels of fine particulate matter (PM_{2.5}) are not being adequately measured near frack sand operations. Air monitors set up by Pierce and his team consistently showed higher readings than detections measured by Wisconsin’s DNR.¹⁰⁸¹ In some instances, PM_{2.5} levels exceeded the EPA guideline of 12 micrograms per cubic meter of air. In an accompanying news story, Pierce noted that the state’s air quality data largely comes from industry itself. “‘The DNR so far has continued to shy away from doing their own monitoring,’ he said. ‘The monitoring I’ve seen so far is inadequate. People aren’t looking at PM_{2.5}, and they really should be—from unbiased sources.’”¹⁰⁸²
- October 15, 2015 – *InsideClimate News* reported on the response of nearby communities to the “bust” cycle of the frack sand industry in Wisconsin and Minnesota. Reactions reported included ongoing concerns that the industry does not provide permanent economic prosperity. Municipalities and community organizations are using the lull to advance protections in advance of a possible upturn: “Towns in the region are also trying to strengthening their local zoning ordinances, such as adding rules to limit industrial noise and light pollution. In other cases, communities are trying to oust pro-sand advocates from office.”¹⁰⁸³
- June 30, 2015 – Because the amount of sand used per fracking well has increased, demand for silica sand by the oil and gas industry is still growing even though new drilling activity has taken a downturn. A global investment bank reported that fracking operations now require an average of 4.2 million pounds of sand per well. A few years

ago, silica sand comprised 9.5 percent of fracking fluid but now is closer to 20 percent. Further “rising intensity” of sand use is expected.¹⁰⁸⁴

- June 15, 2015 – An investigative report by *EnergyWire* documented self-reported health impacts among residents of southwestern Wisconsin who live near silica sand mining operations that service the fracking industry. Exposure to silica dust is a proven cause of silicosis and lung cancer. (See further entries on silica sand exposure among workers in the section, “Occupational Health and Safety Hazards.”) Residents near frack sand mine operations reported exposure to dust pollution and respiratory problems. Air monitoring data from the Wisconsin DNR showed that none of the state’s 63 active sand mines were in violation for particulate matter, but, as the author noted, the state measured particles only 10 micrometers in diameter or larger.¹⁰⁸⁵ Below this diameter, crystalline silica particles are small enough to bypass the body’s natural clearance mechanisms and are likely to lodge deep in the lungs where they can initiate scarring, autoimmune reactions, and tumor formation.¹⁰⁸⁶

Pipelines and compressor stations

There are more than 300,000 miles of natural gas transmission pipelines in the United States. They are serviced, every 40 to 100 miles, by compressor stations that maintain the pressure of the gas flowing through them. (Pump stations do the same for oil pipelines.) Compressor stations and pipelines are significant sources of air pollutants, including benzene and formaldehyde, constituting potential health risks to those living nearby while offering no economic benefits. Instead, they are associated with loss of tax revenue and economic development for the communities where they are sited and which they traverse. Pipelines and compressor stations vent methane into the atmosphere as part of routine maintenance operations and represent a climate risk. They are also accident prone. The Medical Society of the State of New York, the Massachusetts Medical Society, and the American Medical Association have each called for comprehensive health impact assessments regarding the health and safety risks associated with natural gas pipelines, which include fires, explosions, and leaks.

- March 4, 2019 – *E&E News* investigated accidents involving “gathering lines,” which are small diameter pipelines that carry oil or gas from wellheads to processing facilities. Nationally, there are 450,000 miles of gathering lines. However, only high-pressure gathering lines in urban areas are regulated, and these represent only 18,000 miles of

pipeline. The Pipeline and Hazardous Materials Safety Administration (PHMSA) has no rules for the rest. Nor do most states. Hence, it is not known how many fatalities have occurred due to explosions of gathering lines because no records are kept in rural areas. Rural gathering lines “don't have to be marked, built to standards or regularly inspected. Unlike for transmission lines, operators don't have to have emergency response plans for when they leak or explode.”¹⁰⁸⁷

- February 20, 2019 – During a polar vortex on January 30, 2019, a compressor station at an underground gas storage depot in Macomb County, Michigan was destroyed by an explosion after an equipment malfunction triggered emergency venting of gas. The extremely low temperatures prevented the methane plume from dispersing, and high winds pushed it along the ground until the gas encountered heat from another compressor station and exploded. The resulting gas shortage necessitated a statewide emergency call to residents and businesses to voluntarily turn down thermostats and reduce natural gas use. General Motors in Flint suspended operations for three days.¹⁰⁸⁸
- January 1, 2019 – As part of the planned Atlantic Bridge pipeline project, which will ferry fracked natural gas from New Jersey through New England and into Canada, Calgary-based Enbridge Inc. (formerly Spectra Energy) applied to site a 7,700-horsepower compressor station in Weymouth, Massachusetts, south of Boston. The Enbridge compressor station in Weymouth would maintain pipeline pressure needed to push the gas north to Maine and Canada. In 2016, the company offered the town \$47 million to drop its opposition to the plan, which would place the compressor station in a port area immediately adjacent to densely populated neighborhood, the highly utilized Fore River lift bridge, a power plant, a sewage pumping station, and a gas metering station. Instead, residents and local political leaders rejected this offer and demanded a Health Impact Assessment (HIA). Ordered by Governor Charlie Baker in July 2017 and released in January 2019, this study received considerable criticism from the public health community due to its deviation from standard HIA methodologies. The HIA showed that the Fore River Basin already suffered from levels of benzene, formaldehyde, and other air toxics that exceeded state guidelines for these carcinogens while concluding that adding another source of these same pollutants would have negligible impact on residents' health.^{1089, 1090} Shortly thereafter, the Massachusetts Department of Environmental Protection issued an air quality permit for the compressor station. This decision—and the HIA's conclusion on which it was based—was immediately contested

by independent public health researchers. In February 2019, Greater Boston Physicians for Social Responsibility (GBPSR) issued their own report on the health risks of the Weymouth compressor that outlined their concerns about the safety and emergency response hazards associated with the proposed compressor and rejected the “no health impact” conclusion of the HIA. While the HIA acknowledged that the residents of the Fore River Basin already experienced excess rates of lung disease, heart disease, and cancer, the GBPSR report argued that disproportionately health-burdened people “require greater, not lesser, environmental safeguards”^{1091, 1092} At this writing, the air quality permit, which was greenlighted by the HIA’s findings, is under appeal before the Massachusetts Department of Environmental Protection.

- December 18, 2018 – “Given that many pipelines transport volatile, flammable, or toxic oil and liquids, and given the potential consequences of a successful physical or cyber-attack, pipeline systems are attractive targets for terrorists, hackers, foreign nations, criminal groups, and others with malicious intent,” according to a report from the U.S. Government Accountability Office that urged the U.S. Department of Homeland Security’s Transportation Security Administration (TSA) to address weaknesses in its management of pipeline security. TSA oversees the physical security and cybersecurity of the more than 2.7 million miles of gas, oil, and hazardous liquid pipelines in the United States.¹⁰⁹³
- December 14, 2018 – The California Public Utilities Commission (CPUC) took action against Pacific Gas and Electric Company (PG&E) for what CPUC said are systemic violations of rules to prevent damage to natural gas pipelines during excavation activities. PG&E had been noncompliant with the law pertaining to the locating and marking of natural gas distribution pipelines, as well as related requirements to inform construction personnel and private persons on the location of PG&E’s underground pipes and other natural gas infrastructure in a timely and accurate manner.^{1094, 1095, 1096}
- December 10, 2018 – The Atlantic Coast Pipeline is a 600-mile project led by Dominion Energy that would extend from West Virginia to eastern North Carolina. Construction was halted when the U.S. Court of Appeals stayed a permit from the U.S. Fish and

Wildlife Service that had authorized building the pipeline in critical habitat for four endangered species: the Indiana bat, the rusty-patched bumblebee, the clubshell mussel, and a shrimp-like crustacean called the Madison Cave isopod.¹⁰⁹⁷

- November 15, 2018 – An *E&E News* analysis of interstate pipeline enforcement found that interstate pipelines have caught fire or exploded 137 times since 2010. In 90 percent of those disasters, no fines were levied by PHMSA (the federal agency that directly regulates 350,000 miles of pipelines, more than 400 natural gas storage facilities, and 26 liquefied natural gas facilities). PHMSA’s reluctance to levy fines is a direct result of federal pipeline laws, which were largely drafted after 1994 when deregulation was a federal priority.¹⁰⁹⁸
- November 1, 2018 – A Russian team used a cartographic model to assess the potential impact on health and environment of compressor station emissions during scheduled outages and repairs. They described a method of gas flow redistribution that would obviate the need for large-scale venting of methane into the atmosphere.¹⁰⁹⁹
- October 11, 2018 – Overpressurizing a natural gas distribution system while replacing aging pipelines triggered 80 simultaneous natural gas explosions in Massachusetts’ Merrimack Valley on September 13, 2018. One teenager was killed, 23 were injured, 130 buildings were destroyed or damaged, and thousands evacuated from communities in Lawrence, Andover, and North Andover. The explosions cost Columbia Gas more than \$1 billion.¹¹⁰⁰
- September 10, 2018 – A landslide triggered by four days of intense rain caused a pipeline explosion that burned down a house in Beaver County, Pennsylvania and prompted evacuations. This pipeline, built by Energy Transfer Partners (which merged with Sunoco in 2017), was part of the Mariner 2 East Pipeline that is intended to carry the liquid hydrocarbon, ethane, to coastal ports where it will be exported for plastics manufacturing abroad. In western Pennsylvania, ethane co-occurs with methane in the shale bedrock and is released during fracking operations.^{1101, 1102, 1103}

- August 10, 2018 – A joint investigation by the *Charleston Gazette-Mail* and *ProPublica* found that pipeline operators continue to break environmental rules, and state and federal agencies continue to clear roadblocks to allow these projects to move forward despite serious unanswered questions.¹¹⁰⁴
- July 25, 2018 – The Attorneys General of six states (Massachusetts, Rhode Island, New Jersey, Maryland, Illinois, Washington) and the District of Columbia submitted comments to the Federal Energy Regulatory Commission (FERC) on how the Commission should revise its approach to certifying new natural gas transportation facilities. They recommended that the Commission assess need on a comprehensive, regional basis; consider environmental harm, including climate impacts that consider the social costs of carbon; and more heavily weigh the harm of eminent domain. They urged better incorporation of state and local land use policies. And they recommended that the Commission no longer issue partial notices to proceed with construction when rehearing requests are pending.¹¹⁰⁵
- May 24, 2018 – The Office of the Inspector General at the Department of Energy audited FERC’s Natural Gas Certification Process. It found that FERC lacked a consistent process for tracking public comments on proposed pipeline projects, suggesting that all comments might not be reviewed. “In the absence of a consistent methodology, we did not verify to what degree comments received by FERC were considered, aggregated, and reflected in the environmental documents or final orders for the certificate applications during our review,” the report concluded. “The lack of a consistent methodology could increase the risk that FERC may not address significant and impactful public comments in the environmental document or final order.”^{1106, 1107}
- May 16, 2018 – A team of researchers in Alberta, Canada investigated how noise from natural gas compressor stations and oil wells affected the behavior and communication of

Savannah sparrows (*Passerculus sandwichensis*). The results showed that alarm responses and feeding visits were impaired by noise-producing infrastructure. Savannah sparrows were less vigilant when provisioning nestlings and distracted from their reproductive tasks when in the vicinity of compressor stations. “Our observation that Savannah sparrows are less responsive to anti-predator signals in the vicinity of natural gas compressor stations is of conservation concern and adds to a growing body of evidence that noisy anthropogenic structures have the potential to negatively affect birds by interfering with acoustic communication.”¹¹⁰⁸ Previous research in the same region found that the Savannah sparrow altered its song structure and song features when exposed to noise from oil and gas infrastructure, including compressor stations, and that these noise-altered songs were less effective at provoking responses from other birds.¹¹⁰⁹¹¹¹⁰ Similarly, researcher working in the San Juan Basin of New Mexico found that chronic noise from drilling and fracking operations, including compressor stations, affected levels of stress hormones in songbirds and masked critical acoustic cues in ways that decreased the birds’ ability to survive and reproduce.^{1111, 1112}

- April 26, 2018 – Studies that investigate the health impacts of drilling and fracking activities typically incorporate the distance between participants’ home addresses and well pads and do not consider potential exposures to emissions from other ancillary pieces of infrastructure. A study led by Johns Hopkins University researchers working in Pennsylvania attempted to develop exposure metrics for air emissions from compressor stations, flare stacks, and impoundments. The research team identified 457 compressor stations in Pennsylvania and 1419 compressor station engines. Data on compressor stations engines were not available electronically, and only 361 stations could be confirmed as operational. The team found that compressor engines, impoundments, and flaring events are all potential sources of emissions related to drilling and fracking that have not previously been accounted for in epidemiological studies “in part because data are not readily available. The value of including these additional sources of information on [fracking], particularly in health studies, remains unknown.”¹¹¹³

- April 26, 2018 – Pipelines are inspected and cleaned through a process called pigging, in which devices are placed inside, and travel through, the pipe. Pigs can be used to force water or air through a pipeline, check for obstructions, detect leaks, scrape debris from the pipe wall, prevent corrosion, or apply coatings. Pigging is necessarily accompanied by venting of hydrocarbon gases into the air, including methane. A federal settlement acknowledged that the use of the maintenance pigging technique is a major source of harmful emissions in pipeline systems carrying fracked gas extracted from shale that also contains other hydrocarbons, such as natural gas liquids. “The settlement between the U.S. Department of Justice, Environmental Protection Agency and Pennsylvania Department of Environmental Protection and two MarkWest subsidiaries ... alleges the company failed to apply for or comply with air pollution permits. As a result, the company unlawfully vented hundreds of tons of natural gas and volatile organic compounds.”¹¹¹⁴
- October 12, 2017 – Researchers at University of Albany’s Institute for Health and the Environment prepared a 300-page technical report on the health effects of the emissions from 18 natural gas compressor stations in New York State. The team found that, collectively, these sites released 40 million pounds of 70 different contaminants over a seven-year period, making natural gas compressor stations the seventh largest point source of air pollution in the state. By volume, the largest emissions were nitrogen oxides, carbon monoxide, volatile organic compounds (VOCs), formaldehyde, and particulate matter. Exposure to these chemicals is linked to cancer, as well as cardiovascular, neurological, and developmental disorders. The authors noted, “The potential health impacts of the large volumes of pollutants generated by natural gas compressor stations have not been addressed, let alone answered, by those arguing for their construction and expansion.”¹¹¹⁵
- October 11, 2017 – A study of airborne methane emissions from assorted components of natural gas infrastructure in California, including compressor stations and storage facilities, confirmed earlier studies in finding widely variable leakages. The results suggested that a significant fraction of the methane emitted from storage facilities may, in fact, be escaping from their associated compressor stations.¹¹¹⁶
- July 17, 2017 – A comprehensive investigation of the pipeline approval process by the Center for Public Integrity, *StateImpact Pennsylvania*, and National Public Radio found that FERC, which is charged with ensuring the public’s interest, routinely assesses need based on company filings and functions as an agency captured by industry interests, concluding, “at every turn, the agency’s process favors the pipeline companies.” The

¹¹¹⁶ Mehrotra, S., Faloona, I., Suard, M., Conley, S., & Fischer, M. L. (2017). Airborne methane emission measurements for selected oil and gas facilities across California. *Environmental Science & Technology* 51(21), 12981–12987. doi: 10.1021/acs.est.7b03254

result, according to this analysis of more than 500 pipeline cases, is that the financial interests of the gas industry, and not market demand or public necessity, is driving the ongoing pipeline build-out. In some cases, utility companies have complex financial ties to the pipeline companies that service them.¹¹¹⁷ Continuing this investigation, *InsideClimate News* then reviewed several large, new pipeline proposals in the Marcellus and Utica Shale regions, focusing on joint ventures and interlocking financial relationships between customers (state-regulated utilities) and suppliers (pipeline companies). Affiliate agreements that allow parent companies of utilities to seek federal certificates for interstate pipelines—which typically allow a 14 percent return on equity—contribute to the ongoing frenzy of pipeline construction even when natural gas demand is flat. Existing pipelines, the investigation noted, run at only slightly more than half capacity.¹¹¹⁸

- July 12, 2017 – A Canadian study found that oil and gas infrastructure, including compressor stations, contributes to habitat fragmentation and increases parasitism by cowbirds on Savannah sparrow nests in the Northern Great Plains. Populations of North American grassland songbirds, including the Savannah sparrow, are declining precipitously, mostly due to habitat loss and degradation. These results suggest that “brood parasitism associated with oil and natural gas infrastructure may result in additional pressures that reduce the productivity of this declining grassland songbird.”¹¹¹⁹
- May 16, 2017 – An analysis of records from state agencies revealed that low-pressure flow lines at oil and gas well sites are responsible for more than 7,000 spills, leaks, and accidents since 2009. Flow lines carry oil, gas, or wastewater from scattered pieces of equipment within a production site. Other than in New Mexico, operators are not required to report gas leaks from flow lines. A fatal explosion in April 2017 in a Firestone, Colorado home built on top of an oil field was triggered when an abandoned flow line seeped gas into a basement where it ignited. Two people were killed and one person was badly injured. Soon after, Colorado Governor John Hickenlooper ordered a statewide review of all oil and gas lines located near occupied buildings. Preliminary data showed that 16,000 wells across Colorado have flow lines that lie within 1,000 feet of homes. Corrosion is a leading cause of flow line failures.^{1120, 1121}

- February 15, 2017 – A team of researchers from University of Texas investigated emissions from natural gas compressor stations throughout Pennsylvania and New York. They found that compressors emitted highly variable plumes of methane that spread downwind and were measurable a full mile away at levels that could expose nearby residents, especially during temperature inversions. The researchers concluded, “Our data indicate that compressor stations are likely sources of methane emissions and presumably co-emitted air contaminants, and can sporadically/episodically emit methane at relatively high levels...if such facilities are to be permitted to release specified amounts of contaminants, those amounts should be actively measured and verified. Without measurement there can be no assurance that permit conditions are being met.”¹¹²²
- November 30, 2016 – A CityLab investigation used data from the Pipeline and Hazardous Materials Safety Administration to map all significant U.S. pipeline accidents between 1986 and 2016 and concluded, “wherever pipelines are extended, deadly accidents will follow.” Pipeline accidents over the past 30 years have resulted in 548 deaths, more than 2,500 injuries, and over \$8.5 billion in damages. Accidents are particularly common in Texas and Louisiana.¹¹²³
- July 5, 2016 – The National Energy Board, Canada’s pipeline watchdog, gave two of Canada’s largest pipeline companies six months to fix severe deficiencies in pipelines, ultimately issuing an emergency safety order in February 2016. Newly released federal documents showed that Texas-based Kinder Morgan and Alberta-based Enbridge were both looking into the use of defective parts purchased from Thailand-based Canadoil Asia that recently went bankrupt. U.S. regulators warned of these deficiencies eight years prior. At least one Canadian pipeline with defective materials exploded during that period.¹¹²⁴
- June 10, 2016 – EPA Region 2 submitted comments to FERC on Docket Nos. PFI6-3, Eastern System Upgrade Project, which includes new natural gas compressor stations in Hancock and Highland, New York. The EPA submission suggested an analysis of whether this project was needed; clarification of what is meant by a loop system; evaluation of alternatives; a comprehensive analysis of cumulative, indirect, and secondary impacts; information on greenhouse gas emissions and climate change impacts; a Health Impact Assessment; the inclusion of all pollution prevention practices; and a consideration of environmental justice concerns.¹¹²⁵ The company agreed to provide funding toward a health study but wished to retain the ability to determine the

study parameters.¹¹²⁶ Skeptical of the health study's funding and parameters, residents and potentially impacted towns objected to the company's dismissal of the towns' laws prohibiting the construction and operation of heavy industrial use facilities. The Deputy Supervisor of one of the affected towns "said he was encouraged by the federal Environmental Protection Agency's comments on the project's preliminary federal application. He said the EPA concerns were 'the same as ours.'"¹¹²⁷

- April 27, 2016 – In its report on two natural gas pipeline expansion projects in Appalachia, the Institute for Energy Economics and Financial Analysis demonstrated that the Atlantic Coast and Mountain Valley pipelines are “emblematic of the risks that such expansion creates for ratepayers, investors and landowners.” The report concluded that pipelines out of the Marcellus and Utica region are being overbuilt, putting ratepayers at risk of paying for excess capacity, landowners at risk of losing their property to unnecessary projects, and investors at risk of loss. The report stated that FERC facilitates this building of excess pipeline capacity and its approach for assessing need is insufficient.¹¹²⁸
- April 22, 2016 – The federal Agency for Toxic Substances and Disease Registry (ATSDR) released a report on air quality near a natural gas compressor station in Brooklyn Township, Susquehanna County, Pennsylvania, finding levels of fine particulate matter (PM2.5) at levels that can damage human health in those with long-term exposure. Evaluating data from an 18-day EPA field air monitoring event, the report found that the average ambient 24-hour PM2.5 concentration observed at one residence (19 µg/m3) was higher than the nearest regional National Ambient Air Quality Standards (NAAQS) monitoring station (12.3 µg/m3) in Scranton, PA, over the same period. ATSDR concluded that there was evidence that long-term exposure to PM2.5 at the levels found can cause an increase in mortality, respiratory problems, hospitalizations, preterm births, and low birth weight. The agency said that in the short term, exposure could be harmful to sensitive populations, such as those with respiratory problems or heart disease. The agency recommended that sensitive individuals monitor air quality and limit activity accordingly, and that the PA DEP work to reduce other sources of PM and its precursors.¹¹²⁹
- April 3, 2016 – The Southwest Pennsylvania Environmental Health Project issued a *Technical Report* in response to the January 29, 2016 federal ATSDR report on the Brigich compressor station in Chartiers Township, Washington County, Pennsylvania.

ATSDR detected chemicals that had been reported at gas sites previously, and this confirmation of their presence provided “an important acknowledgement that neighbors of such facilities are being exposed (often at very close range) to chemicals that bring with them the possibility of short- and long-term health effects.” The report stated that, in conjunction with the monitoring work of the EPA, ATSDR “provided a solid set of data.” However, due to the limitations of the methodologies available to them, the authors were “concerned that there was, in the end, an underestimate of risk to community members.”¹¹³⁰

- April 1, 2016 – Kinder Morgan, the largest energy infrastructure company in North America, suspended construction of a \$1 billion pipeline project that would have carried gasoline and diesel fuel across the southeastern United States. Construction was suspended after landowners protested the seizure of their property, a Georgia Superior Court judge upheld a decision denying a certificate that would have allowed the company to use eminent domain, and the state legislature passed legislation to block the property seizure.¹¹³¹
- March 26, 2016 – According to a Boston University-led study, fugitive emissions from urban natural gas pipeline systems were the largest anthropogenic source of the greenhouse gas methane in the United States and contribute to the risk of explosions in urban environments, with 15 percent of leaks qualifying as potentially explosive.¹¹³² “All leaks must be addressed, as even small leaks cannot be disregarded as ‘safely leaking,’” concluded the report authors. In an interview with *InsideClimate News*, the lead author said that in addition to weighing the safety risks from gas leaks, regulators and utility companies must also consider the climate impact of leaks when determining priorities for repairing and replacing pipes.¹¹³³
- March 7, 2016 – A lawsuit filed against FERC in U.S. District Court in Washington, D.C. challenged the agency’s relationship with industry, reported *Penn Live*: “The suit accuses the commission of regulatory capture, a situation in which corporations control regulators.” FERC receives all of its funding from the energy companies that it regulates and had never rejected a pipeline plan, which, according to the complainant, demonstrates “clear bias and corruption.”¹¹³⁴

- February 26, 2016 – Congressman Chris Gibson (NY-19), in response to citizen concerns, sent a letter to FERC regarding the proposed 41,000-horsepower compressor station in southern Rensselaer County, New York, part of the Northeast Energy Direct (NED) pipeline project. He discussed the inadequacy of federal exposure standards with regard to exposures at compressor sites and lack of medical expertise in these decisions. He requested public health expertise on all Environmental Assessment and Environmental Impact Statement teams, an independent panel to review the federal exposure standards around compressor stations, and “a transparent and effective review process.”¹¹³⁵ His call was supported by other elected officials, as well as public health researcher David O. Carpenter, MD, who has studied compressor station pollutants.¹¹³⁶
- January 29, 2016 – ATSDR, in collaboration with the EPA Region 3 Air Protection Division, conducted an exposure investigation to evaluate exposures of residents living near the Brigich natural gas compressor station in Chartiers Township, Washington County, Pennsylvania. ATSDR concluded that, although exposure to the levels of chemicals detected in the ambient air was not expected to harm the health of the general population, “some sensitive subpopulations (e.g., asthmatics, elderly) may experience harmful effects from exposures to hydrogen sulfide and PM 2.5 [and] [s]ome individuals may also be sensitive to aldehyde exposures, including glutaraldehyde.” According to ATSDR, one of the study’s limitations was that the sampling “may not have adequately captured uncommon but significant incidents when peak emissions (e.g. unscheduled facility incidents, blowdowns or flaring events) coincide with unfavorable meteorological conditions (e.g. air inversion).” ATSDR recommendations included reducing exposures to the chemicals of concern to protect sensitive populations, continued collection of emissions data for long-term and peak exposures, and air modeling to better understand ambient air quality.¹¹³⁷
- December 8, 2015 – The Niagara County Legislature, following the recommendations of the Medical Society of the State of New York, called for a Health Impact Assessment (HIA) on natural gas infrastructure, including compressor stations, and co-hosted a conference in Albany on the Medical Society’s health findings. A compressor station with twin compressors, part of the “2016 Northern Access Plan” to transfer gas from Pennsylvania to Canada, is proposed for the county.¹¹³⁸

- November 9, 2015 – Following the 2010 heavy oil spill in Michigan’s Kalamazoo River, Congress ordered an audit that spotlighted the industry’s poor record of spotting leaks. *Politico* reported on the 2015 regulatory structure ultimately unveiled in response, determining the proposal “fails to patch that hole in the nation’s pipeline safety net.” “While the agency’s proposed rule expands the number of pipelines that must have a leak-detection system in place, it sets no basic standards for how well that technology should work. Instead, safety advocates say, it lets pipeline operators decide for themselves whether they are adequately prepared.”¹¹³⁹
- October 16, 2015 – The EPA urged FERC to consider “whether the Northeast Energy Direct pipeline could be combined with other projects, rather than constructing a new system that would have a host of environmental impacts,” reported Oneonta, New York’s *Daily Star*. The EPA also advised “that the gas demand addressed by NED’s application could be met by renewable forms of energy such as solar and wind power...”¹¹⁴⁰ (Note: Kinder Morgan withdrew its NED pipeline application in April 2016.)
- September 17, 2015 – At a shale gas conference, industry representatives espoused the construction of new pipelines as necessary to re-invigorate the gas industry in the Marcellus. Speakers noted that FERC approval can be expected to now take longer, by about six months, blaming environmental groups for the delays.¹¹⁴¹
- September 9, 2015 – New pipelines are failing at a rate on par with gas transmission lines installed before the 1940s, according to an analysis of federal data by the Pipeline Safety Trust, reported by *S&P Global Market Intelligence*. “The gas transmission lines installed in the 2010s had an annual average incident rate of 6.64 per 10,000 miles over the time frame considered, even exceeding that of the pre-1940s pipes. Those installed prior to 1940 or at unknown dates had an incident rate of 6.08 per 10,000 miles.” The director of the National Transportation Safety Board’s Office of Railroad, Pipeline and Hazardous Materials Investigations “agreed that the rapid construction of pipelines in the U.S. is likely a contributing factor.”¹¹⁴²
- August 18, 2015 – Houston Advanced Research Center (HARC) scientists addressed “the commonly acknowledged sources of uncertainty which are the lack of sustained monitoring of ambient concentrations of pollutants associated with gas mining, poor quantification of their emissions, and inability to correlate health symptoms with specific emission events.” They concluded that “more contemporary monitoring and data analysis techniques should take the place of older methods to better protect the health of nearby

residents and maintain the integrity of the surrounding environment.” “Real-time mobile monitoring, microscale modeling and source attribution, and real-time broadcasting of air quality and human health data over the World Wide Web” have been demonstrated, they wrote, by past, current, and planned future monitoring studies in the Barnett and Eagle Ford shale regions.¹¹⁴³ Founded as a technology incubator in 1982 by Houston oilman George P. Mitchell, HARC later re-aligned to focus on sustainable development.

- August 14, 2015 – HARC scientists found that port operations involving petrochemicals may significantly increase emissions of air toxics, including peaks of carcinogenic benzene of up to 37 ppb. The scientists matched the benzene spikes with pipeline systems. The spikes were at levels much higher than those reported in the EPA’s 2011 National Emissions Inventory. The authors recommended the use of updated methods for ambient monitoring.¹¹⁴⁴ Lead scientist Jay Olaguer said in a related interview that “government regulators should wake up to the reality of the situation, that their methods of tracking air pollution need to be updated so that the samples are taken in real time and can catch it when toxic vapors of this magnitude are released.”¹¹⁴⁵
- July 15, 2015 – Rensselaer County lawmakers passed a resolution asking the state of New York to freeze the approval process for the Northeast Energy Direct pipeline—which would carry fracked gas from Pennsylvania to Boston—until it conducts a comprehensive health impact assessment for natural gas pipelines.¹¹⁴⁶
- July 8, 2015 – Researchers from West Virginia University completed leak and loss audits for methane emissions at three natural gas compressor stations and two natural gas storage facilities, with a “leak” defined as an unintended release of natural gas due to malfunction of a component, and a “loss” defined as an intended release of natural gas. In terms of frequency, most emissions were leaks, but on a mass basis, losses were the dominant source of methane emissions (88 percent). The top loss emitters were engine exhausts (accounting for nearly half), packing vents, and slop tanks. Emissions from compressor blowdowns were not included.¹¹⁴⁷ A related study by a University of Houston

team found that emission rates from compressor stations in Texas' Barnett Shale were far higher than from well pads.^{1148, 1149}

- July 7, 2015 – Seeking a method to bridge the gap between bottom-up and top-down methods of measuring methane emissions, Purdue University, University of Houston, the National Oceanic and Atmospheric Administration (NOAA), Environmental Defense Fund, and independent researchers surveyed eight high-emitting point sources in the Barnett Shale using an aircraft-based “mass balance” approach. Results from four gas processing plants and one compressor station highlighted the importance of addressing methane “super-emitters” and confirmed that self-reports from the Greenhouse Gas Reporting Program underestimated actual emission rates by a factor of 3.8 or higher, due to “underestimated facility emissions, temporal variability of emissions, and the exclusion of nonreporting facility emissions.”¹¹⁵⁰
- July 7, 2015 – Using relatively easy-to-acquire and inexpensive stable isotopic and alkane ratio tracers, researchers are now able to distinguish methane arising from natural gas production and transport from agricultural and urban methane sources, and, in addition, to distinguish between methane released from shale gas as opposed to conventional wells. Initial research from the University of Cincinnati, University of California at Irvine, and the Environmental Defense Fund found that methane in the Barnett Shale hydraulic fracturing region near Fort Worth, Texas, represents a complex mixture of these sources. This new approach, used for ground-level measurements, can complement and extend top-down approaches, allowing for more accurate inventories of thermogenic and biogenic sources of methane emissions.¹¹⁵¹
- July 1, 2015 – In New York State, Schoharie County supervisors and medical professionals demanded comprehensive health impact assessments as a precondition for permitting natural gas pipelines and compressor stations.¹¹⁵²
- June 12, 2015 – The Agency for Toxic Substances and Disease Registry investigated the health effects of ruptured gas pipelines in an analysis of data in a database on acute petroleum-related releases to which seven states contribute (Louisiana, New York, North Carolina, Oregon, Tennessee, Utah, and Wisconsin). From 2010 to 2012, there were

1,369 such incidents, which resulted in 259 injuries. More than three-quarters of these incidents were related to natural gas distribution. Equipment failure accounted for half of all incidents; human error accounted for 40 percent. The report noted the “continuing occurrence” of petroleum release incidents—including from natural gas pipeline ruptures—which have “the potential to cause mass casualties and environmental contamination.”¹¹⁵³

- June 9, 2015 – The American Medical Association (AMA) adopted a resolution, “Protecting Public Health from Natural Gas Infrastructure,” that was based on a resolution adopted by the Medical Society of the State of New York. (See below.) The resolution states, “Our AMA recognizes the potential impact on human health associated with natural gas infrastructure and supports legislation that would require a comprehensive Health Impact Assessment regarding the health risks that may be associated with natural gas pipelines.”¹¹⁵⁴
- May 2, 2015 – The Medical Society of the State of New York adopted a resolution, “Protecting Public Health from Natural Gas Infrastructure,” that recognizes the potential impact to human health and the environment of natural gas pipelines and calls for a governmental assessment of these risks.¹¹⁵⁵
- March 3, 2015 – Researchers with the Southwest Pennsylvania Environmental Health Project measured ambient levels of particulate and volatile air pollutants from fracking-related operations and calculated expected human exposures in Washington County, Pennsylvania. Extremely high exposures peaked at night when air was still. These fluctuating exposure events mimic, in frequency and intensity, the episodic nature of health complaints among residents. Over a one-year period, compressor stations were responsible for more extreme exposure events (118) than well pads or gas processing plants.¹¹⁵⁶
- February 24, 2015 – As part of a literature review on the health impacts of compressor stations, the Southwest Pennsylvania Environmental Health Project reported that peak emissions of fine particles tended to occur during construction time, that day-to-day emissions during operational time can fluctuate greatly, and that a compressor blowdown typically represented the single largest emission event during operations. Hence, documentation of these fluctuations cannot be captured by calculating yearly averages. A blowdown is an intentional or accidental release of gas through the blowdown valve that

Human exposure to unconventional natural gas development: a public health demonstration of periodic high exposure to chemical mixtures in ambient air. *Journal of Environmental Science and Health, Part A: Toxic/Hazardous Substances and Environmental Engineering*, 50, 460-72. doi: 10.1080/10934529.2015.992663

creates a 30- to 60-meter-high gas plume. Blowdowns, which are used to release pressure, can last as long as three hours. The authors noted that blowdowns result in periods of high levels of volatile organic compound releases and that anecdotal accounts associate blowdowns with burning eyes and throat, skin irritation, and headache.¹¹⁵⁷ There is neither a national or state inventory of compressor station accidents nor a body of peer-reviewed research on the public health impacts of compressor stations.

- February 17, 2015 – A Boston study found that emissions from residential, end-use natural gas infrastructure was a significant source of atmospheric methane—two to three times larger than previously presumed—and accounted for 60 to 100 percent of methane, depending on the season. Of all the natural gas in the downstream component of the natural gas system, 2.7 percent was lost to the atmosphere.¹¹⁵⁸
- February 10, 2015 – A team of engineers from Pennsylvania and Colorado examined methane emissions from natural gas compressor stations and found that vents, valves, engine exhaust, and equipment leaks were also major emissions sources. There was considerable variation in emissions among the 45 compressor stations measured. Surprisingly, substantial emissions were found even when compressors were not operating.¹¹⁵⁹
- December 27, 2014 – A *Pittsburgh Tribune-Review* investigation found that the vast majority of natural gas “gathering lines”—pipelines that take natural gas from rural well pads to processing plants—were regulated by neither federal nor state pipeline safety laws. The United States has nearly 230,000 miles of natural gas gathering lines that are unregulated, operating without safety standards or inspection. These pipelines are among the largest and highest-pressure pipes in use and carry gas at nearly three times the pressure of transmission lines, which transport the gas from the processing plants to urban distribution networks.¹¹⁶⁰
- November 11, 2014 – An analysis by a Carnegie Mellon University research team of 40,000 pipeline accidents from 1968 to 2009 found that comparatively few accidents accounted for a large share of total property damage, whereas a large share of fatalities and injuries were caused by numerous, small-scale accidents. There are 2.4 million miles

of natural gas pipeline in the United States and 175,000 miles of hazardous liquid pipeline (which includes crude oil).¹¹⁶¹

- October 30, 2014 – A research team led by David O. Carpenter at University at Albany found high levels of formaldehyde near 14 compressor stations in three states. In Arkansas, Pennsylvania, and Wyoming, formaldehyde levels near compressor stations exceeded health-based risk levels. The authors noted that compressor stations can produce formaldehyde through at least two routes: it is created as an incomplete combustion byproduct from the gas-fired engines used in compressor stations. It is also created when fugitive methane, which escapes from compressor stations, is chemically converted in the presence of sunlight. Formaldehyde is a known human carcinogen. Other hazardous air pollutants detected near compressor stations in this study were benzene and hexane. One air sample collected near a compressor station in Arkansas contained 17 different volatile compounds. (See entry for October 30, 2014 in Air Pollution.)
- October 15, 2014 – In comments to FERC, New York’s Madison County Health Department reviewed the literature on compressor station emissions and expressed concerns about associated health impacts, including documented correlations between health problems and residential proximity to compressor stations. It also reviewed health outcomes associated with exposures to chemicals known to be released from compressor stations, including VOCs, carbonyls and aldehydes, aromatics, and particulate matter. In addition, gas from fracking operations transiting through compressor stations may carry gaseous radon. The Health Department noted a troubling lack of information on the intensity, frequency, and duration of emission peaks that occur during the blowdowns and large venting episodes that are a normal part of compressor operations.¹¹⁶²
- September 16, 2014 – Noting the proximity of a proposed high-pressure pipeline to Indian Point Nuclear Facility, as well as the evidence linking compressor station emissions to negative health impacts, New York’s Rockland County legislature adopted a resolution calling for a comprehensive Health Impact Assessment in regards to Spectra Energy’s planned Algonquin Incremental Market (AIM) natural gas pipeline, compressor, and metering stations expansion project.¹¹⁶³ This resolution follows on the heels of similar resolutions expressing health concerns about the AIM project from both Westchester and Putnam County legislatures.^{1164, 1165}

- January 24, 2013 – A report prepared for the Clean Air Council by an independent consulting firm to evaluate air quality impacts from the Barto Compressor Station in Penn Township, Lycoming County, Pennsylvania predicted “large exceedances” of the nitrogen dioxide (NO₂) 1-hour NAAQS. Researchers used allowable emissions in the PA DEP permit, the 2006-2010 meteorological data and the latest EPA modeling guidance for the model’s prediction. Three techniques were used, and for two of the techniques, NAAQS exceedances occurred within a mile of the plant. The report concluded, “NO₂ impacts from the Barto plant alone are very significant since its emissions cause large exceedances of the 1-hour NAAQS.”¹¹⁶⁶
- July 13, 2011 – A Fort Worth air quality study assessed the impact of drilling and fracking operations, and ancillary infrastructure, on concentrations of toxic air pollutants in the city of Fort Worth, Texas. The study found that compressor stations were a significant source of fracking-related air pollution. The compressor engines were responsible for over 99 percent of the hazardous air pollutants emitted from compressor stations, of which 67 percent was formaldehyde.¹¹⁶⁷

Gas storage

Gas storage facilities include not only manmade holding tanks but also geological formations, most notably, aquifers, abandoned salt caverns, and depleted oil fields left over from mining and drilling operations. These unlined cavities were not created with the intent to store pressurized hydrocarbon gases, nor are they engineered for this purpose. The 3,600-acre Aliso Canyon gas storage facility, located in a depleted oil field in southern California, released more than 100,000 metric tons of methane into the air of the San Fernando Valley over a four-month period beginning in October 2015 before it was finally contained in February 2016. This massive methane leak—the largest in U.S. history—is the greenhouse gas equivalent of a half million cars driving for a year. The plume itself was visible from space. More than 8,000 families in the nearby community of Porter Ranch were evacuated and

relocated, thousands were sickened, and two public schools closed. The immediate cause of the Aliso Canyon blowout was a cracked well casing and lack of a shut-off valve. Data released in 2018 as part of a new U.S. Department of Transportation rule reveal that there are more than 10,000 Aliso-style storage wells with gas flowing through only a single unprotected pipe—that is, with a single point of failure. Of the nearly 400 natural underground storage facilities in the United States, 296 of them have one or more of these wells, and they are located in 32 states.

- February 1, 2019 – An assessment of gas leakage from different types of natural gas storage facilities that established a mathematical model to predict leakage points showed that long-term periodic injection of gas and improper construction will lead to some degree of gas leakage risks, no matter what kind of construction process is used to create the gas storage reservoir.¹¹⁶⁸
- January 2, 2019 – Plans by Alton Natural Gas to create a massive gas storage hub in salt caverns north of Halifax, Nova Scotia were delayed due to “project and regulatory planning,” and the company has asked the Nova Scotia Utility and Review Board to extend its cavern construction permit. The plan involves hollowing out underground salt deposits using water from the tidal Shubenacadie River. The brine waste would then be dumped into the river, twice a day at high tide, over a two- to three-year period. Members of the Sipekne’katik First Nation argue that the project will harm the ecology of the tidal river, which runs through the middle of Nova Scotia. They have continuously occupied and protested at the site since 2014.¹¹⁶⁹
- August 20, 2018 – A research team investigated the geomechanics of an underground natural gas storage facility in China. They noted that geological factors and engineering factors can both contribute to leaks. Engineering factors include problems with casing integrity, cementing quality, and salt cavern operating pressure. Geological factors include challenges posed by the complexity of geological formations, imperfect sealing by the caprock, and the presence of faults. Using geological analysis, permeability tests, and CT scans, the authors determined that the risk of leakage in this salt cavern underground gas storage arises mainly from a failure of wellbore tightness within a mudstone interlayer.¹¹⁷⁰
- July 12, 2018 – The New York State Department of Environmental Conservation denied a permit for liquified petroleum gas storage (propane) in abandoned salt caverns on the shoreline of Seneca Lake. “The record demonstrates that the impacts of this project on

the character of the local and regional community, including but not limited to the environmental setting and sensitivity of the Finger Lakes area and the local and regional economic engines (e.g., wine, agricultural and tourism industries), are significant and adverse and the project does not avoid or minimize those impacts to the maximum extent practicable. Furthermore, the significant adverse impacts on community character are not outweighed or balanced by social, economic or other considerations, and cannot be avoided or minimized to the maximum extent practicable by the proposed mitigation measures.” Concerns were also raised about the structural integrity of the caverns following disclosure by the gas storage company that additional pressure testing in the caverns would be required to assess possible leaks.^{1171, 1172} The previous year, a subsidiary of the same company scrapped a parallel plan to expand the storage of natural gas in adjacent salt caverns along the lake shore.¹¹⁷³

- June 22, 2018 – A research team undertook an analysis to determine why the roof of China’s first salt cavern underground gas storage facility collapsed, as determined by a sonar test after just 1.3 years of use. They concluded that the main reasons for the collapse were the large-span flat roof, a too-rapid decrease in internal gas pressure, and localized damage that led to massive collapse. They also concluded that this cavern has a high risk of roof collapse taking place again. The study includes evaluations of other similar incidents worldwide. Using geomechanical modeling, the authors developed a “new failure prediction index, consisting of volume shrinkage, dilatancy safety factors, displacement, vertical stress, and equivalent strain.”¹¹⁷⁴
- May 4, 2018 – A new Department of Transportation rule requires gas companies that operate storage facilities to disclose information about design, leaks, and repairs of their wells. According to data released on April 4, 2018 as part of this rule, more than 10,000 wells have gas flowing through only a single unprotected pipe—that is, with a single point of failure. Of the nearly 400 natural underground storage facilities in the United States, 296 of them have one or more of these wells, and they are in 32 states.¹¹⁷⁵ These statistics update an earlier estimate by Harvard University researcher Drew Michanowicz,

who, consulting earlier databases, had pegged the number of Aliso-type wells at about 2,700.¹¹⁷⁶ (See also entry for May 24, 2017.)

- March 6, 2018 – Illinois has the largest amount of natural gas storage in salt formations in the nation. Some of these storage sites underlie the Mahomet Aquifer, which provides drinking water for 14 counties in east-central Illinois. Prompted by an October 2016 report by a federal task force in the aftermath of California’s Aliso Canyon natural gas leak, a team from the University of Illinois’ Prairie Research Institute created an introductory guide to provide basic information about the Mahomet Aquifer and natural gas storage in east-central Illinois.¹¹⁷⁷ (See also entry for October 18, 2016.)
- January 18, 2018 – The California Council of Science and Technology released a 910-page report analyzing the safety risks of all 14 facilities in the state that store gas in depleted oil fields. Among its findings: gas companies do not disclose the chemicals that are pumping underground; state regulators lack necessary information to assess risks; and many wells servicing the storage fields are 60 to 90 years old with no regulatory limit to the age of the well.¹¹⁷⁸
- December 1, 2017 – A University of Southern California-led team investigated the root causes of the catastrophic Aliso Canyon gas storage blow-out, which began October 23, 2015 and continued for four months before being contained. Using methodology designed to capture both social and technological factors, the team concluded that corporate dysfunction and lack of government oversight were the driving forces responsible for the accident. “Risk analysis is vital for safe well operations and relies on analyzing prior data records, yet no national standards for well records were in place prior to the accident. There was no clear overarching agency that was in control of the accident’s intervention and aftermath.”¹¹⁷⁹ In a subsequent news piece from the university, Najmedin Meshkati, senior author of the study, said, “SoCal Gas had lenient requirements for infrastructure record keeping, no comprehensive risk management plan, and no testing programs or plans in place to remediate substandard wells. The company needs to improve its safety culture.”¹¹⁸⁰

¹¹⁷⁶ Michanowicz, D. (2018, May 14). The Aliso Canyon gas leak was a disaster. There are 10,000 more storage wells out there just like it. *Los Angeles Times*. Retrieved from <http://www.latimes.com/opinion/op-ed/la-oe-michanowicz-aliso-canyon-gas-leak-20180514-story.html>

¹¹⁸⁰ Vuong, Z. (2018, February 15). Who should be held responsible for the Aliso Canyon gas leak? *USC News*. Retrieved from <http://news.usc.edu/136300/who-should-be-held-responsible-for-the-aliso-canyon-gas-leak/>

- November 22, 2017 – The U.S. Government Accountability Office (GAO) reported that, two years after the Aliso Canyon blow-out, the Pipeline and Hazardous Materials Safety Administration (PHMSA) is failing to inspect natural gas storage sites in a timely manner, as called for by the Department of Transportation’s interim standards. Until 2016, states set the standards for 211 of the nation’s 415 gas storage sites, while the 204 sites that were connected to interstate pipelines had no standards at all. Collectively, these 415 natural gas storage sites contain about 17,000 wells that inject or withdraw natural gas from the underground formations below, which include depleted oil and gas reservoirs, abandoned mines, depleted aquifers, and hard rock caverns. The GAO noted that more than 300 cities and towns are located near natural gas storage sites.¹¹⁸¹
- June 21, 2017 – In response to requests from the oil and natural gas industry, the White House announced that it will delay implementation of a rule that would have set national standards for underground natural gas storage. Prompted by the 2015 disaster at Aliso Canyon and developed under the previous administration, this federal interim rule had called for phasing out single-point-of-failure, single-containment designs of the type that made impossible the task of swiftly shutting off the impaired Aliso Canyon well once it began leaking.¹¹⁸²
- May 24, 2017 – A national assessment of thousands of underground gas storage wells by a Harvard School of Public Health team found that more than 20 percent are similar in design to the well that failed at Aliso Canyon. These obsolete wells, with single failure points and a median age of 74 years, operate in 19 states and represent more than half of the working capacity for U.S. natural gas. More than 2,700 of these wells were not originally designed to hold gas and, as at Aliso Canyon, have been repurposed to do so. An estimated 210 of these repurposed wells (located in Pennsylvania, Ohio, New York, and West Virginia) are more than 100 years old and entirely lack cement zonal isolation methods. Study author Jonathan Buonocore said, “Partly because no federal safety regulations apply to natural gas storage wells or their operations (now pending), very little aggregate information was available. . . . After we identified this data gap, we realized we needed to build our own database to begin to assess this previously inapparent hazard.” With the 50 percent increase in domestic natural gas production over the last ten years, natural gas storage is at an all time high and in demand.^{1183, 1184}

- October 21, 2016 – The California Air Resources Board determined that the Aliso Canyon gas storage facility released 100,000 tons of methane, becoming the largest ever natural gas leak in U.S. history.¹¹⁸⁵
- October 18, 2016 – A federal task force issued a report with 44 recommendations intended to prevent another Aliso Canyon-style disaster. Chief among them is a phase-out of “single-point of failure” designs.¹¹⁸⁶
- July 13, 2016 – As reported by the *Los Angeles Daily News*, Los Angeles County health officials were prepared to go to court to ensure that the Southern California Gas Company complies with an order to pay for professional comprehensive cleaning in the homes of residents who were relocated due to the Aliso Canyon gas leak. The company had filed legal papers asking that the order “to remove dust and oily mist from up to 35,000 homes be nullified,” after their report of having cleaned 1,700 homes to date. The Los Angeles County Health Department said the company had done a poor job on these and did not follow protocol to remove the metal particles, including barium, manganese, vanadium, aluminum, and iron previously identified in household surface dust.¹¹⁸⁷
- July 9, 2016 – California’s South Coast Air Quality Management District and Southern California Gas Company were still at an impasse seven months after the company was given an abatement order that included a community health study on the potential impacts of exposures from the massive Aliso Canyon leak. The company was ordered to commit to paying “reasonable costs” for the study.¹¹⁸⁸
- June 22, 2016 – The first federal legislation of gas storage facilities was signed into law. The Protecting our Infrastructure of Pipelines and Enhancing Safety Act of 2016 includes a provision in response to the Aliso Canyon gas leak requiring PHMSA to develop regulations for the construction and operation of underground natural gas storage facilities.¹¹⁸⁹ (See entry below, of February 8, 2016, for analysis of the likely shortcomings of these first federal regulations and their inability to prevent a leak such as that at Aliso Canyon.)

- June 20, 2016 – As reported in *Geophysical Research Letters*, an airborne instrument onboard a NASA satellite was able to detect and quantify the size and shape of the methane plume from the Aliso Canyon gas leak as the event occurred.¹¹⁹⁰ This is the first time a natural gas leak has been visible from space, according to the authors of the study.¹¹⁹¹
- May 4, 2016 – Southern California Gas Company said that costs related to the Aliso Canyon natural gas storage facility leak reached an estimated \$665 million. The utility company let the Securities and Exchange Commission know they carry policies with a combined limit available “in excess of \$1 billion,” but according to the *Los Angeles Times*, legal experts and lawyers said that \$1 billion in insurance might not be enough for what they ultimately need.¹¹⁹²
- April 12, 2016 – California energy agencies issued a report indicating the threat of widespread summer power outages if no gas can be withdrawn from Aliso Canyon. The report was met with criticism. “Consumer groups and utility critics contend that the blackout warnings are an irresponsible scare tactic to ensure that Southern California Gas Company is allowed to keep storing gas at the facility and that ratepayers will pay for upgrades to store even more fuel there.”¹¹⁹³
- April 6, 2016 – The *Los Angeles Times* reported that, though prices for homes in Porter Ranch adjacent to the Aliso Canyon gas storage leak held up, sales declined. After the leak that began October 23, 2015, sales from December 2015 to February 2016 declined 20 percent from the year before. Disclosures for homes in the area “now include a mention of the community's proximity to the gas field and the recent problems.”¹¹⁹⁴
- March 18, 2016 – The California State Oil and Gas Division of the Department of Conservation issued penalties totaling \$75,000 for three separate violations after finding incidents of intentional venting of gas at the Aliso Canyon gas field and malicious concealment of those acts. Both are violations of the state gas regulations.¹¹⁹⁵ Following the Aliso Canyon gas storage leak, the California State Public Utilities Commission ordered a statewide survey of California’s 12 natural gas storage fields and found 229

faulty valves, flanges and leaky wellheads and a 230th leak at an abandoned well; eight were deemed hazardous.¹¹⁹⁶

- March 14, 2016 – Methane and ethane emissions were measured to determine spatial patterns and source attribution of urban methane in the Los Angeles Basin. The surveys demonstrated the prevalence of fugitive methane emissions across the Los Angeles urban landscape and that fossil fuel sources accounted for 58–65 percent of methane emissions.¹¹⁹⁷
- February 25, 2016 – Measurements of methane and other chemicals were taken by aerial equipment following the October gas release from a faulty well in the Aliso Canyon storage field. The data demonstrated that the blowout of this single well created the largest known anthropogenic point source of methane in the United States. The leak lasted 112 days and released a total of 97,100 tons of methane and 7,300 tons of ethane into the atmosphere. This was equal to 24 percent of the methane and 56 percent of the ethane emitted each year from all other sources in the Los Angeles Basin combined.¹¹⁹⁸ Aliso Canyon was already a major pollution source before the massive leak.¹¹⁹⁹ As determined by the study and reported by major news outlets, the recent methane leak is officially the worst in U.S. history.^{1200, 1201}
- February 18, 2016 – Stanford and UCLA scientists reported to *InsideClimate News* that the lack of measurement data for the entire 100+ days of community exposures to the Aliso Canyon methane leak, combined with gaps in the science about many of the chemicals, hinders the ability to understand the health impacts of the leak. “‘The first week is when we would expect the highest gas concentrations to reach the neighborhood because the pressures in the storage field were the highest,’ said Robert Jackson, an earth system science professor at Stanford University who measured methane concentrations in nearby communities during the leak. ‘And yet we don't have any information or data for

that first week at least.” Jackson noted that even after monitoring was initiated, it was intermittent rather than continuous.¹²⁰²

- February 18, 2016 – Independent regional experts from USC and UCLA interviewed by Southern California Public Radio expressed skepticism that an industry-funded study ordered by the South Coast Air Quality Management District following the Aliso Canyon methane leak would be rigorously designed to answer specific questions about sub-chronic, cumulative exposures, including hydrogen sulfide, which was measured in the nearby Porter Ranch community at levels far greater than the average across American cities.¹²⁰³
- February 13, 2016 – The Los Angeles County Department of Health prepared a *Supplemental Report* for its Expanded Air Monitoring Plan concerning the Southern California Gas Company’s Aliso Canyon storage facility long-term gas leak. The report addressed “chemicals of health concern” including toluene, ethylbenzene, xylene, hydrocarbons, VOCs, metals, and radon and concluded, “all results suggest that chemical exposures experienced by residents as a result of the gas leak are below the levels of concern that have been established by various regulatory agencies.”¹²⁰⁴ Remaining challenges named by the report itself included possible gaps in data collection, other chemicals present for which no sampling occurred, and further study of the symptoms reported by the public. Many independent scientists did not concur with the Department of Health’s ongoing statements that chemical exposures were below levels of concern. Issues raised included monitoring not initiated until a week after the leak began, lack of continuous monitoring, and reliance on “grab samples.” Speaking to *InsideClimate News*, John Bosch, a retired air-monitoring expert with more than 30 years’ experience at the EPA said, “Grab samples may be OK as a first-tier guesstimate of what the problem is, but you really have to have continuous monitoring.”¹²⁰⁵
- February 8, 2016 – PHMSA announced that it might issue its first federal safety regulations for gas storage sites such as Aliso Canyon, while also suggesting site operators voluntarily follow guidelines that the proposed rules (which would likely take years to issue) will likely mirror. According to a report in *InsideClimate News*, these guidelines would not require systems to stop the flow of gas in an emergency or mandate redundancies to prevent methane from leaking into the environment.” If PHMSA

proceeds to adopt industry guidelines, the resulting rules “may not address two key issues that turned Aliso Canyon into a disaster: emergency shutoff valves and a safer configuration of pipes.” Further, even with new regulations, storage units would most likely remain under state jurisdiction, “though state authorities may adopt any new federal rules.”¹²⁰⁶ A subsequent story reported on members of Congress pressing PHMSA to create the first federal standards for the 418 underground gas storage facilities for which it has authority to set regulations. In the hearing before a subcommittee of the House Committee on Transportation and Infrastructure, California representatives “spoke about their efforts to speed up PHMSA’s rulemaking for underground gas storage.”¹²⁰⁷

- February 5, 2016 – As part of the Expanded Air Monitoring Plan, Los Angeles County Department of Health provided results for the primary chemicals of concern to assess health effects in residents, pets, and other animals in the community during the Southern California Gas Aliso Canyon storage facility leak. Those chemicals included methane, odorants, and benzene. The maximum level of methane detected was 4,340 ppm and the maximum level of benzene was 30.6 ppb. Early on, average weekly benzene levels that were close to the 1 ppb chronic exposure limit/ health protective level. “Methane levels have remained above normal, but have decreased substantially over time,” the report summarized. It also stated that odorants “. . . remained below instrument detection limits throughout the entire period, including immediately after the leak, even at locations near the leaking well,” and that “[b]enzene and other chemicals were originally detectable at levels above normal from within community sampling sites, but peak levels remained below acute exposure thresholds.”¹²⁰⁸ While the Los Angeles County Department of Health concluded that “health effects resulting from the on-going leak should be limited to short-term effects resulting from exposure to the odorants,” independent scientists, noting data gaps, have challenged these conclusions.
- January 25, 2016 – Some health experts and residents of Porter Ranch, California, adjacent to the Aliso Canyon gas field leak, expressed concern about long-term exposure to the odorous component of the gas, mercaptans, to which regulators attributed several symptoms of residents. Mercaptans are sulfurous chemicals that are added to natural gas to aid in the detection of leaks. Though California regulators have said the health problems, such as headaches, vomiting, and nosebleeds are temporary and will not lead to long-term damage, medical researchers described data gaps to *InsideClimate News*. There is “virtually no research on prolonged exposure to mercaptans.” Further, some researchers suggest the health problems may have been caused by different chemicals in

¹²⁰⁶ McKenna, P. (2016, February 8). New federal gas storage regulations likely to mimic industry's guidelines. *InsideClimate News*. Retrieved from <https://insideclimatenews.org/news/08022016/federal-gas-storage-regulations-likely-mimic-industry-guidelines-aliso-canyon-phmsa-api>

the gas, and that “regulators have downplayed the significance of other contaminants that are also present in the leak.”¹²⁰⁹

- January 19, 2016 – Peter Richman, MD, president of the Los Angeles County Medical Association told the *Los Angeles Daily News* that, at nearly three months after the Aliso Canyon methane leak began, physicians had yet to receive a formal statement from the Los Angeles County Department of Public Health about airborne chemical pollutants related to the gas leak or guidelines on how to answer questions from patients about long-term health effects. Richman expressed special concern about prolonged exposure to methane and trace chemicals known to be carcinogenic. Another area physician reported that, as of the interview date, his urgent care practice had seen a hundred patients whose symptoms were consistent with exposure to leak-related pollutants.¹²¹⁰
- January 14, 2016 – Boston University researcher Nathan Phillips and Bob Ackley of Gas Safety USA drove a high precision GIS-enabled gas analyzer through roads throughout California’s San Fernando Valley adjacent to the Aliso Canyon gas leak in early January 2016. Early results showed methane levels elevated 2-67 times the background level.¹²¹¹
- January 13, 2016 – Investigations into the possible cause of the gas leak in Aliso Canyon included the consideration that nearby fracking may have contributed to casing failure. In an email to the *Los Angeles Daily News*, California Department of Conservation Chief Deputy Jason Marshall said that their investigation will examine well records, including those pertaining to “well stimulation operations.”¹²¹² According to a 2015 report prepared for the California Council on Science and Technology, hydraulic fracturing is used about twice yearly to enhance storage “mostly in one facility serving southern California (Aliso Canyon).”¹²¹³
- January 13, 2016 – “Aliso Canyon is a wake-up call,” according to a *Rocky Mountain PBS News* investigative report on the state of U.S. natural gas infrastructure. Natural gas is no longer a cleaner fuel than coal when methane leakage rates exceeds 2-4 percent, but the vast size of the nation’s interconnected natural gas storage and pipeline systems

¹²⁰⁹ Song, L. (2016, January 25). Mercaptans in methane leak make Porter Ranch residents sick, and fearful. *InsideClimate News*. Retrieved from <https://insideclimatenews.org/news/22012016/porter-ranch-residents-health-effects-methane-leak-aliso-canyon-california>

makes difficult the task of tallying all the micro-leaks spread across the entire network and answering fundamental questions about exactly how much methane is being lost. The PBS report also expressed concern about the age of many of the system's component parts. According to the piece, nearly half (46 percent) of the nation's transmission pipelines, designed to carry high-pressure gas over long distances, were built in the 50s and 60s and are now more than a half century old.¹²¹⁴

- December 30, 2015 – According to the *Los Angeles Daily News*, which unearthed November 2014 state regulatory filing documents, the Southern California Gas Company knew about the corrosion and potential for leakage at Aliso Canyon prior to the massive blow-out. “In written testimony to the California Public Utilities Commission, [SoCalGas Director of Storage Operations Phillip] Baker described a reactive maintenance process that hinted at major leakage problems underground.”¹²¹⁵
- November 20, 2015 – California state agencies collaborated with Aviation Scientific to measure methane emission rates at two early November dates, finding rates of 44,000±5,000 kilograms of methane per hour and 50,000±16,000 kilograms of methane per hour. The results indicated that the Aliso Canyon gas leak would have contributed about a quarter of California's methane emissions for the time period studied.¹²¹⁶
- November 20, 2015 – According to the *Los Angeles Times*, one month into the Aliso Canyon ongoing gas leak, Southern California Gas warned that it “might need several months” to plug the leak. An order from California's Division of Oil, Gas and Geothermal Resources, “stated that an ‘uncontrolled flow of fluids’ and gas was escaping and the operator had failed to fully inform state officials about the well's status. Steve Bohlen, the state oil and gas supervisor, also directed the company to submit a schedule for remediation work or for drilling a relief well.”¹²¹⁷
- October 19, 2015 – *Houston Public Media* reported on the 125 caverns carved out of salt storing natural gas liquids (NGLs), thousands of feet under the city of Mont Belvieu, Texas, east of Houston. “There have been fiery accidents here. But nothing like what happened 23 years ago at a different [NGL] storage site 100 miles to the west. ‘A bomb-like blast literally blew residents in this small community out of their beds this morning, said a reporter for Dallas's Channel 8 as he did a live report just outside the city of Brenham.’ That blast, which killed three and injured 21, was reportedly caused by the

lack of an emergency shut-off valve. There are no federal standards in place for such requirements. Twenty-three years later, a month prior to the *Houston Public Media* report, “at a hearing held by the U.S. Senate Committee on Commerce, Science, & Transportation, Donald Santa, head of the Interstate Natural Gas Association of America, told the senators that it was only in recent weeks that the industry approved standards for storing natural gas.” Texas did enact legislation a year after the deadly blast “and now requires emergency shutoff valves and inspections for leaks every five years.”¹²¹⁸

- October 5, 2011 – The federal district court in Topeka struck down Kansas gas-safety laws in 2010, and 11 underground storage sites with a capacity of more than 270 billion cubic feet of gas have gone uninspected, leaving thousands of Kansans to live on and around uninspected gas-storage fields.¹²¹⁹
- 2008 – When considering the possibility of storing natural gas in a variety of underground gas storage facilities, the UK government commissioned the British Geological Survey to identify the main types of facilities currently in operation worldwide along with any documented or reported failures and incidents which have led to release of stored product. The researchers found that California had the most incidents, but concluded that many of these problems and geological factors would not necessarily be applicable to the UK. The incidents most relevant to gas storage in the UK resulted from a failure of either the man-made infrastructure (well casings, cement, pipes, valves, flanges, compressors etc.), or human error, which has included overfilling of caverns and inadvertent intrusion. Extreme natural events, including earthquakes, also played a role. The researchers looked closely at incidents in salt caverns that had been repurposed to store gas. They reported that “early salt cavern storage in the US was done in brine wells that had been solution mined [in which salt deposits are melted away with hot water or steam] without consideration for subsequent storage in the depleted caverns. This practice sometimes resulted in later problems for storage operations in retrofitted brine caverns.” The authors conclude that the rate for a geological failure of the storage cavity in an underground gas storage facility is of the order of 10^{-5} failures per well year.¹²²⁰

Liquefied natural gas (LNG) facilities

LNG is methane vapor that has been turned into liquid through a cryogenic process that lowers the temperature of the gas to its condensation point (– 259° F). Chilling natural gas to its liquid state shrinks its volume by a factor of 600, allowing LNG to be transported to places

where pipelines don't reach, as when it is exported overseas on massive tanker ships. LNG is also sometimes used as vehicle fuel in, for example, long-haul trucks. LNG facilities encourage fracking by creating storage for the glut of gas that fracking has created, by enabling its export, and by driving up prices and profit margins. LNG facilities are capital-intensive and consist of liquefaction plants, import/export terminals, tanker ships, regasification terminals, and inland storage equipment.

LNG liquefaction requires immense energy in order to achieve the ultra-low temperatures required for condensation. An LNG facility typically requires its own power plant. Because they rely on evaporative cooling, LNG tanks are leaky by design: to maintain the liquid at super-chilled temperatures and prevent explosions, vaporized gas is vented from storage tanks directly into the atmosphere. Larger tanks are engineered to capture boiled-off gas, but this process is not leak-proof. Before it is combusted or sent down a pipeline, LNG must be regasified via an energy-intensive process that requires massive infrastructure of its own, including periodic flaring to control pressure. Refrigeration, venting, leaks, flaring, and shipping make LNG more energy intensive than conventional natural gas. A recent analysis shows that exporting large quantities of LNG from the United States will likely cause global greenhouse gas emissions to rise not only because of its energy penalty but also because LNG exports add more fossil fuels to the global market and extend the lifespan of U.S. coal-fired plants.

LNG creates acute public safety risks. LNG explodes when spilled into water and, if spilled on the ground, can turn into rapidly expanding, odorless clouds that can flash-freeze human flesh and asphyxiate by displacing oxygen. If ignited at the source, LNG vapors can become flaming "pool fires" that burn hotter than other fuels and cannot be extinguished. LNG fires burn hot enough to cause second-degree burns on exposed skin up to a mile away. LNG facilities pose significant risks to nearby population centers and have been identified as potential terrorist targets.

- July 13, 2018 – A retrospective look at the risk management and risk governance used to develop and construct three LNG facilities in Gladstone, Australia evaluated the process by which multiple stakeholders—including government, business, community, and environmental groups—contributed to decision-making and management. The framework developed by the International Risk Governance Council was used for comparison. Environmental, social, and economic impacts occurred during construction, including death of harbor marine life, increased housing prices, and increased cost of living. Several problems in risk assessment and management were identified, including lack of cooperation between organizations at the onset of construction; disagreement as to whether monitoring and compliance mechanisms were adequate; and concern that the government was reactive to problems, rather than attempting to prevent or mitigate risks. Several recommendations were made to improve the risk management process of future projects.¹²²¹

¹²²¹ van der Vegt, R. G. (2018). Risk assessment and risk governance of liquefied natural gas development in Gladstone, Australia. *The Extractive Industries and Society*, 6(1), 58-66. doi: 10.1111/risa.12977

- February 12, 2018 – Two LNG storage tanks were shut down at Cheniere Energy’s Sabine Pass export facility after leaking LNG was found in a containment ditch around one of the tanks and 14 separate natural gas leaks were discovered around the base of a second tank. The Sabine Pass facility is located on the U.S. Gulf Coast on the border between Texas and Louisiana. Emergency procedures were put into place to assure the safety of the 107 on-site workers, but the public was not notified about this incident until more than two weeks later. Inspection revealed four cracks up to six feet long in the outer shell of the tank that had leaked LNG. These tanks are double walled, but only the inner tank is designed to tolerate the super-chilled temperature of LNG. The outer tank, rated to only -25° F, became brittle upon contact with -260° F LNG. The resulting investigation uncovered a long history of safety issues at this plant, including 11 other incidents involving these tanks that had occurred as far back as 2008 (when Sabine Pass was operating as an LNG import facility) after the federal Pipeline and Hazardous Materials Safety Administration (PHMSA) ordered Cheniere to conduct a root cause analysis and turn over records of any prior leaks.¹²²² The agency also issued an order stating, “continued operation of the affected tanks without corrective measures is or would be hazardous to life, property, and the environment.” Sabine Pass facility was required to receive written authorization from the Federal Energy Regulatory Commission (FERC) before the tanks could be put back in service.¹²²³ As part of a later hearing, parts of which were closed to the press and to the public, an accident investigator with PHMSA said that she had struggled with the company to get information “timely and in enough detail.”¹²²⁴ In April 2018, the parties agreed to resolve the issue without administrative proceedings or litigation.¹²²⁵
- November 20, 2017 – Using a hybrid lifecycle and energy strategy analysis, a team of energy researchers investigated the potential climate impacts of U.S. LNG exports to Asia. They found that gas emissions were widely variable, dependent on the specific destination and the ultimate purpose for which the gas is used. Despite this range, under a scenario in which U.S. LNG exports continue to rise, “emissions are not likely to decrease and may increase significantly” because of additional energy demand, higher U.S. emissions, and increased methane leakage. The study also predicted that increased LNG exports could actually prolong the lifespans of coal-fired plants within the United States. All together, these factors, “have the very real potential to undermine any prospective climate benefit in the long run.” Going forward, policymakers must consider “the complete climate ramifications of LNG exports.”¹²²⁶ *E&E News*, reporting on the study, quoted one of the authors as saying, “The implications of our paper are that the

greenhouse gas impacts from exporting U.S. natural gas...here at home and abroad, can be very, very bad.”¹²²⁷

- November 16, 2017 – A legal analysis in the *Energy Law Journal* examined the contested decision by the Federal Energy Regulatory Commission to authorize the expansion of the Dominion Cove Point LNG facility to allow for export as well as import activity, by examining the multiple direct and indirect effects of the expansion. Direct effects included impacts on water quality, the North Atlantic right whale, and the public safety of local residents. Indirect effects included an increase in domestic fracking, increase in tanker traffic, and exacerbation of climate change as export markets increase demand for natural gas. Because this latter set of problems is not directly related to facility expansion but rather to increased LNG exports, two different federal agencies have jurisdiction. The responsibilities of FERC and the Department of Energy (DOE) were clarified regarding this distinction. FERC handles the environmental review, while the DOE regulates export of LNG. In the case of Cove Point, FERC had issued a finding of no significant impact and was therefore not legally required to investigate indirect effects such as climate change. The analysis therefore concluded that FERC followed proper procedures and that the DOE would be a more appropriate target of legal action because of its control over LNG exports. This analysis reveals the diffusion of responsibility among federal agencies regulating LNG facilities and the legal difficulties of addressing far-removed, indirect harms.¹²²⁸
- July 25, 2017 – Citing volatile market conditions, Malaysia’s energy giant Petronas cancelled plans for a massive LNG export terminal at the mouth of the Skeena River on British Columbia’s remote northwest coast in Canada. As reported extensively by *The Tyee*, the project was the target of intense protest by First Nations people and the subject of many lawsuits, as it threatened public health and would industrialize pristine salmon habitat. “At one time as many as twenty LNG projects were proposed for coastal communities, but not one has been built. The majority of largely Asian-backed proponents have now cancelled or deferred their projects. A 50 percent drop in global oil prices combined with a 70 percent drop in global LNG prices forced Petronas to...scuttle a number of projects over the last two years.”¹²²⁹
- July 10, 2017 – Using a lifecycle assessment and optimization analysis to forecast the environmental impacts of LNG, researchers modeled three usage scenarios: hydrogen production; electricity generation; and vehicle fuel. The model assumed LNG transport by pipeline only, and not by tanker. The highest environmental impact in each case was

global warming potential (GWP), and the highest GWP occurred when LNG was used as vehicle fuel.¹²³⁰

- April 11, 2017 – The World Bank Group, which makes loans to developing nations for capital projects like infrastructure, released environmental, health, and safety guidelines for LNG facilities. These guidelines address the risks of spills, fire, explosions, air quality impacts, venting, flaring, and fugitive emissions. Also addressed was the danger of “roll-over,” a phenomenon that occurs when layers of LNG of different density in a storage tank mix inappropriately. The result can be a rapid release of vapors and rise in pressure, potentially leading to catastrophic structural damage of the tank.¹²³¹
- March 30, 2017 – Transportation researchers identified and assessed potential risks to public safety from LNG transport on inland waterways and as a fuel for vessels and ferries. The hazards included the possibility of collision with other ships or with stationary objects such as bridges, as well as the threats of vapor release, flash and jet fires, boiling liquid expanding vapor explosion, and rapid phase transition. Firefighting strategies for different scenarios were proposed.¹²³²
- March 9, 2017 – Liquefaction, LNG transport, and LNG evaporation determined more than 50 percent of LNG’s global warming potential (GWP) in a “cradle to gate” life cycle analysis of LNG imported to the UK from Qatar. The analysis confirmed the dangerous effect of fugitive methane emissions on the total GWP of the supply chain. Other important parameters affecting GWP included the shipping distance and the tank volume.¹²³³
- December 22, 2016 – Methane emissions from the heavy-duty transportation sector have climate change implications, according to a “pump-to-wheels” evaluation of natural gas powered vehicles and the compressed natural gas and LNG stations that fuel them. While fueling stations themselves leak methane, tailpipe and crankcase emissions were the highest sources.¹²³⁴
- May 2, 2016 –The potential economic and greenhouse gas (GHG) impacts of importing LNG to Hawaii for electricity generation was modeled. Methane is a potent GHG, and although the use of LNG would decrease the local GHG output of Hawaii’s electrical

sector, lifecycle (global) GHG emissions would likely increase. This study did not examine other potential environmental impacts of LNG. Currently, the majority of Hawaii's electricity is provided by oil-fired generation.¹²³⁵

- November 12, 2015 – New York Governor Andrew Cuomo rejected a heavily contested proposal to construct an LNG terminal 19 miles off the coast of Long Island. From his letter to the Maritime Administration: “The security and economic risks far outweigh any potential benefits....The potential for disaster with this project during extreme weather or amid other security risks is simply unacceptable.” The governor also noted the risks posed to scallop and squid fisheries as well as the project's conflict with a proposed large-scale, offshore wind farm.¹²³⁶
- September 30, 2015 – Measurements of the gaseous and particulate emissions of a cruise ferry on the Baltic Sea using a dual-fuel engine showed that LNG is not a clean fuel for ships. Methane made up about 85 percent of the vessel's hydrocarbon emissions. Particulate emissions showed a huge amount of volatile and nonvolatile particles, both of which are hazardous to human health.¹²³⁷
- September 26, 2014 – The U.S. Government Accountability Office (GAO) issued a report of the federal process for reviewing applications to export LNG. As part of the process, the DOE and FERC consider public comment. Numerous environmental concerns include the risk that exports will increase hydro-fracking for natural gas, along with its associated environmental effects and greenhouse gas emissions. Under the National Environmental Policy Act, the DOE must consider the environmental effects of its decisions.¹²³⁸
- April 23, 2014 –The dynamics and hazards from a LNG spill are not well understood and require further research, according to a comprehensive review of research into the LNG production chain from Australia that examined vapor production, vapor dispersion, and mechanisms of combustion. Noting the “intrinsic process safety issues” of LNG as well as potential attraction as a terrorist target, authors described various threats to human safety, including pool fires, jet fires, and vapor cloud explosions.¹²³⁹
- December 14, 2009 – Certain LNG hazards are not “understood well enough to support a terminal siting approval,” according to a Congressional Research Service (CRS) report that summarizes LNG hazards in the context of federal rules related to where LNG

terminals are located. Potential risks include pool fires and flammable vapor clouds, as well as the possibility of terrorist attacks. The analysis points out the need for additional LNG safety research.¹²⁴⁰

- July 7, 2009 – Because LNG projects are among the most expensive energy projects, the reserves of gas to justify the investment need to be large enough to guarantee about 30 years of production, according to a report by the Joint Research Centre of the European Union.¹²⁴¹
- May 13, 2008 – LNG infrastructure is “inherently hazardous and it is potentially attractive to terrorists,” according to a CRS study that was prepared at a time when the United States was a net importer of LNG. Security of tankers, import terminals, and inland storage plants were identified as issues of concern. Serious risks include pool fires with intense heat, which can occur when LNG spills near an ignition source; flammable vapor clouds that can drift until reaching an ignition source; and a rapid phase transition that can generate a flameless explosion. As per this report, there have been 13 serious accidents at onshore LNG terminals since 1944.¹²⁴²
- February 22, 2007 – The GAO examined the results of studies on the consequences of an LNG spill and discussed expert opinion about the consequences of a terrorist attack on an LNG tanker. The studies indicate that 30 seconds of exposure to the heat of an LNG fire could cause burns up to a distance of about one mile. The experts concluded that this would be the most likely public safety hazard, with the risk of explosion less likely. Recommendations were made for further studies, including evaluating the possibility of “cascading failure,” where multiple LNG tanks on a ship might fail in sequence.¹²⁴³
- September 9, 2003 – As part of a larger investigation of potential terrorist targets in wake of the 9/11 attacks, the CRS provided a background report to the U.S. Congress on the security of LNG terminals in the United States. At the time, the United States was a net importer of natural gas, and LNG was shipped from overseas to U.S. ports. CRS identified LNG tanker ships and storage infrastructure as “vulnerable to terrorism,” noting that tankers could be turned as weapons against coastal cities and that inland LNG facilities are typically located near large population centers. The CRS further noted that

the public cost of security for LNG shipments, via Coast Guard escorts of tankers through coastal shipping channels, was considerable (\$40,000-\$80,000 per tanker).¹²⁴⁴

- August 1, 1995 – The U.S. Department of Transportation identified three important hazardous properties of LNG: flammability hazards (fire or explosion from ignition of leaks); toxicity hazards (asphyxiation from exposure to non-odorized fuel gas); cryogenic hazards (personal injury plus structural failure of equipment from prolonged exposure to extremely cold temperatures.)¹²⁴⁵

Gas-fired power plants

Found in every state except Vermont, natural gas-fired power plants surpassed coal-burning plants as the leading source of electrical generation in the United States in 2016. There are two types of gas-fueled power plants: combined cycle plants and simple cycle plants. Both types are major emitters of carbon dioxide, uncombusted methane, and nitrogen oxides, which contribute to the formation of ground-level ozone (smog). Combined cycle gas plants reuse waste heat to generate additional electricity and are roughly equivalent in efficiency to an older coal plant. Simple cycle gas plants—also called peaker plants—can be turned on and off faster to meet fluctuating energy demands when electricity needs peak, but they are much less efficient and more polluting than combined cycle plants. Simple cycle peaker plants can often generate more nitrogen oxides and more carbon monoxide than coal plants.

Gas-fired combined cycle plants were formerly promoted as a bridge to reduce emissions while renewables ramp up. However, within the last four years, renewable prices have fallen low enough to allow a transition directly from coal to solar and wind power, revealing that gas plants, with long returns on investment, are more barrier than bridge to renewable energy. At the same time, the lifecycle emissions of both types of gas-fired power plants have been shown to be far higher than previously estimated. New natural gas plants lock in demand for gas for longer than current climate scenarios dictate, which call for net-zero carbon emissions by mid-century. Gas plants thus risk becoming stranded assets, meaning that they would need to be decommissioned well before the end of their lifespan.

Gas-fired simple cycle plants used on demand as peakers are becoming obsolete as battery technology now allows for the storage of renewable energy, decreasing the need for gas plants to provide power in times of peak demand.

Emerging evidence shows a variety of health impacts to people living near gas-fired power plants.

- February 11, 2019 – The mayor of Los Angeles announced that the city will close rather than modernize three gas-fired power plants after the California legislature passed a bill requiring the state to get 100 percent of its electrical power from climate-friendly sources by 2045. Instead, the city will pursue clean energy technologies with battery storage. The Scattergood, Haynes, and Harbor natural gas plants will be phased out by 2029.¹²⁴⁶ In a press statement, Los Angeles mayor Eric Garcetti said, “This is the beginning of the end of natural gas in Los Angeles. The climate crisis demands that we move more quickly to end dependence on fossil fuel, and that’s what today is all about.”¹²⁴⁷
- February 8, 2019 – The Arizona Corporation Commission voted to extend the state moratorium on buying or building new gas-fired power plants and called for energy storage to provide peak power rather than additional natural gas plants.¹²⁴⁸
- April 1, 2018 – Integrating environmental, economic, and social factors to evaluate overall sustainability, a British team compared shale gas with other electricity options in the United Kingdom. Fracking emerged as one of the least sustainable ways to produce electricity. Specifically, shale gas ranked seventh out of nine options for electrical generation, with wind and solar energy scoring the best and coal the worst. These results suggest that “a future electricity mix ... would be more sustainable with a lower rather than a higher share of shale gas.”^{1249, 1250}
- July 14, 2017 – A European team evaluated the performance of coal- and gas-fired power plants that are used to back up renewable energy as the European Union transitions to greater reliance renewable sources for electrical generation. As renewables increasingly dominate, traditional fossil fuel plants will be required to ramp up and down and cycle on and off more frequently, However, these ramping and cycling events will negatively impact the operation of the fossil fuel power plants, as they will become fatigued, resulting in higher operational and maintenance costs, reduced lifetime, degraded performance, and higher emissions of air pollution over time. Gas plants are generally more efficient, faster, and less polluting than coal, but under certain conditions will

produce more nitrogen oxides (a component of smog) and more carbon monoxide than coal-fired plants. Current fossil fuel technology will need significant and costly improvements in order to handle the increased gradients, number of starts, lower minimum load and emissions.¹²⁵¹

- February 1, 2017 – There is a high degree of uncertainty about the methane emissions from natural gas-fired power plants. As part of a study that also included oil refineries, a Purdue University team evaluated methane emissions from three gas-fired power plants in Utah, Indiana, and Illinois during hours of peak operation. Both fugitive methane leaks from the facility at large as well as uncombusted methane from the stacks were measured using aircraft. Results showed that average methane emission rates were larger than facility-reported estimates by factors of 21-120. The authors concluded that gas-fired power plants “may be significant contributors to annual methane emissions in the U.S. despite lack of facility emission reporting in U.S. inventories. Furthermore, results suggest that the primary source of methane emissions at these facilities may be from noncombustion sources.”¹²⁵²
- June 28, 2015 – Pregnant women living near gas-fired power plants were more likely to give birth prematurely, according to a study of more than 400,000 infants born in Florida between 2004 and 2005. This study investigated associations between adverse birth outcomes and residential proximity to several types of power plants, including those burning oil, gas, and solid waste.¹²⁵³
- September 22, 2012 – An investigation of methane and nitrous oxide emissions at eight different gas-fired power plants in Korea found that emissions can vary depending on combustion technologies. Results from this study differed both from those used as default emission rates by the Intergovernmental Panel on Climate Change and from those measured in Japan. The authors concluded that technology-specific and country-specific emission factors for gas-fired power plants need to be established.¹²⁵⁴
- February 27, 2012 – Using hospitalization data, a research team working in New York State examined whether living near a fuel-fired power plant increased the rate of hospitalization for asthma, acute respiratory infections, and chronic obstructive pulmonary disease, all of which have known links to air pollution exposure. Preliminary analyses of hospitalization rates associated with a residence in a zip code with a power plant stratified by type of fuel used (coal, gas, oil, or solid waste) did not show clear or

A study on the evaluations of emission factors and uncertainty ranges for methane and nitrous oxide from combined-cycle power plant in Korea. *Environmental Science and Pollution Research*, 20(1), 461-468. doi: 10.1007/s11356-012-1144-1

consistent patterns. Therefore, patients were classified as exposed if they lived in a zip code with at least one power plant in it regardless of the type of fuel used. After adjusting for age, sex, race, median household income, and rural/urban residence, the research team found significantly elevated rates of hospitalization for asthma (11 percent increase), acute respiratory infection (15 percent increase), and chronic obstructive pulmonary disease (17 percent increase) among New Yorkers living near at least one fuel-fired power plant.¹²⁵⁵

- October 20, 2011 – Emergency room visits and hospital admissions in elderly people living close to a new gas-fired power plant in Italy were counted and related to levels of air pollution both before and after the plants became operational. The results showed that ambient levels of nitrogen oxides and particulate matter rose after the plant started operations. Further, despite the fact that pollutants were below the limits set by the European legislation, there was a positive correlation between number of emergency room visits and daily concentrations of these air pollutants among nearby residents aged 70 or older.¹²⁵⁶
- April 5, 2010 – Most new fossil fuel power plants are gas-powered. In this study, a research team estimated the number of premature deaths from fine particulate matter that would result from bringing 29 proposed fossil-fuel power plants in Virginia on line. Their modelling predicted that, were all 29 plants made operational, concentrations of fine particulate air pollution would rise in 271 counties across 19 states. Over a six-year period, 104 cumulative excess deaths would occur due to operations of these proposed plants.¹²⁵⁷

Inaccurate jobs claims, increased crime rates, threats to property values and mortgages, and local government burden

According to multiple studies in multiple states, the oil and gas industry's promises of job creation from drilling for natural gas have been greatly exaggerated. Many of the jobs are short-lived, have gone to out-of-area workers, and, increasingly, are lost to automation. With the arrival of drilling and fracking operations, communities have experienced steep increases in rates of crime, variously including assault, rape, sex trafficking, larceny, and auto theft. In the Marcellus Shale region, violent crime increased 30 percent in counties that experienced a fracking boom compared to those without fracking. Aggravated and sexual assaults were the crimes primarily responsible for this increase. Crime rates have increased even with additional allocation of funds for public safety. Financial and other strains on municipal services include those on law enforcement, road maintenance, emergency services, and public school district administration. In Texas alone, road damage and other transportation impacts costs an estimated \$1.5-\$2 billion a year. In shale boom areas across the United States, school districts report heightened stress, regardless of whether student funding increased or decreased. Economists are increasingly quantifying community quality of life impacts and the unequal distribution of costs and benefits associated with drilling and fracking. Drilling and fracking pose an inherent conflict with mortgages and property insurance due to the hazardous materials used and the associated risks. With the departure of drilling and fracking operations from these communities, some of the challenges are eased. However, such departures can also lead to additional economic harms, such as by sharp upticks in foreclosures, late car and mortgage payments, empty housing units, and failed or diminished local businesses.

- March 14, 2019 – A Canadian team reviewed the research published between 2009–2018 on the impacts on communities of “the whole suite of technologies that aid in the exploration, extraction, and transportation” of natural gas. This first review of impacts across the supply chain found most of the studies addressed upstream communities (those adjacent to the gas extraction), and that midstream and downstream communities were understudied. Midstream communities were those located in transportation corridors, such as near pipelines, and downstream communities were those near processing and shipping facilities. The study identified 28 community impacts across four broad categories: environmental impacts; impacts to infrastructure and service delivery; impacts on policy, regulation, and participation in decision-making; and socioeconomic impacts. In each area, the reviewers identified common findings, mixed results across studies, and research gaps. For social service delivery, for example, the review found significant effects from the boom and bust cycles. In the boom cycle these included “increased pressure on limited infrastructure, affordable housing and daycare, recreational and child/youth programs, and social services to address alcohol and drug addictions, domestic violence, and crime.” In the bust cycle there is a continued need for social services, especially as created by unemployment, economic hardship, local business closures, dropping property values, and out-migration. In this period though, there may

be cuts to social services, and “peer-reviewed articles rarely focused on the capacity of local governments to address impacts before, during, and after they happen.”¹²⁵⁸

- December 10, 2018 – Although Pennsylvania has been able to realize modest short-term economic growth from fracking, policy researchers found that the state has also allowed costs to be externalized to public health, the environment, and community integrity. Despite emerging evidence on adverse public health effects, there remain significant uncertainties about these externalized costs, especially with regard to the long term. Research done in the state has shown “significant remaining uncertainties in detecting and attributing responsibility for groundwater contamination” associated with fracking. Intensive gas extraction in Pennsylvania can strain communities by several pathways: increased demand for emergency medical and mental health services; loss of housing for low income residents displaced by temporary, out-of-state workers; and increased traffic violations and arrests for driving under the influence. Emergencies at fracking sites can also strain or exceed the capabilities of local emergency response organizations. At the state level, policy weaknesses include failure to mandate the disclosure of fracking chemicals, failure to exercise adequate inspection and enforcement, and failure to institutionalize “stewardship of rents extracted from a nonrenewable resource for future generations.”¹²⁵⁹
- November 21, 2018 – The presence of drilling and fracking operations is linked with fewer visits to overnight recreation sites in National Forests in western states. As part of a USDA Forest Service study that analyzed visitor use data from 27 National Forests with 722 overnight use areas, researchers found that, on average, each additional oil or gas well within a five-kilometer radius of a site was linked to six fewer visits annually. Within a five-kilometer radius, the distance between the well and the campground was not a significant factor. The researchers did not speculate on the overall user experience but wrote that their results do “suggest that the presence of oil and gas development may have a significant enough effect on the user experience to motivate users to recreate elsewhere.”¹²⁶⁰
- October 28, 2018 – In 15 states between 2000 and 2013, intensive shale oil and gas drilling activity was linked with 41,760 fewer students enrolled in school per year in grades 11 and 12. This phenomenon was greatest in states with a younger compulsory schooling age (16 years of age instead of 17 or 18), in states with a lower effective tax rate on oil and gas production, and in rural counties with traditional mining or persistent poverty.¹²⁶¹ The results of the study, conducted by a team of economists, aligned with

A cross-sectional analysis of overnight recreation site use at 27 national forests with oil and gas development. *Journal of Outdoor Recreation and Tourism*. 24, 45-51. doi: 10.1016/j.jort.2018.11.001

¹²⁶¹ Zuo, N., Schieffer, J., & Buck, S. (2019). The effect of the oil and gas boom on schooling decisions in the U.S. *Resource and Energy Economics*, 55, 1-23. doi: 10.1016/j.reseneeco.2018.10.002

historical evidence from the 1970s energy boom as well as complementary research from the 2000s, both showing that oil and gas booms “can discourage educational attainment by increasing the opportunity cost for students to stay in school.” (See entry below for July 2015.)

- September 24, 2018 – An *E&E* investigation examined cities in North Dakota, Pennsylvania, and Oklahoma that are experiencing lingering financial and social disruptions following oil and gas booms. In Oklahoma, “the state Legislature is trying to fix what some viewed as a string of bad fiscal decisions that led to cuts in education and other services.” In Pennsylvania, communities are still roiled by “a series of bitter disputes about whether local landowners were getting their fair share of royalties from gas drilling.” In North Dakota, the debt held by the city of Williston was high for a town its size, with its manageability dependent on continuing oil tax income from the state.¹²⁶²
- August 22, 2018 – Marking a decade since Marcellus Shale fracking began in earnest, a five-university research team presented a review of impacts to people, policy, and culture in the greater mid-Atlantic region of the United States. The review’s geographic and thematic sections address a range of impacts on Pennsylvania communities and a discussion of the less-studied communities in West Virginia and Ohio undergoing fracking. Economic impacts in Pennsylvania, contrary to what political and business interests typically tout, are mixed. Employment data showed that positive effects for local residents “are relatively small and temporary, in large part because much of the employment benefits from the activity goes to workers living outside the host communities.” Further, among local residents, economic benefits were unequally distributed based on land ownership. In Pennsylvania, about half of lease and royalty dollars accrue to the top 10 percent of local landowners who owned the most acreage, while the bottom 70 percent of landowners collectively receive only 2.8 percent of all such dollars. “The vast majority of local residents were not rural landowners and thus were unable to take advantage of gas leasing for revenue.” For poorer residents in fracking areas, “radically tightening housing markets, coupled with skyrocketing housing costs,” presented fundamental economic hardships.¹²⁶³
- June 6, 2018 – Uneven distribution of economic/service-related benefits and social/environmental costs characterize the Barnett and the Eagle Ford shale plays in Texas, according to an analysis of shale energy development in the southern United States that included both objective and perceived effects. Transportation-related hazards, deemed “the big one,” were seen as the primary concern to community leaders and residents. Multiple sources and study types corroborated the objective transportation trends and harms. For example, a survey of county and city public officials in the 15-county Eagle Ford Shale region concluded that increasing transportation demands resulting from fracking “have not been met with needed state resources to maintain

¹²⁶² Lee, M., & King, P. (2018, September 24). These places rode out the boom and bust. Now what? *E&E News*. Retrieved from <https://www.eenews.net/stories/1060099341>

¹²⁶³ Jacquet, J. B., Junod, A. N., Bugden, D., Wildermuth, G., Fergen, J. T., Jalbert, K., . . . Ladlee, J. (2018). A decade of Marcellus Shale: Impacts to people, policy, and culture from 2008 to 2018 in the Greater Mid-Atlantic region of the United States. *The Extractive Industries and Society*, 5, 596-609. doi: 10.1016/j.exis.2018.06.006

and/or upgrade transportation facilities to meet the increased volume and weight of vehicles using the transportation system in local communities.” An Academy of Medicine, Engineering and Science of Texas Task Force on Environmental and Community Impacts of Shale Development in Texas likewise concluded, “the level of funding to address the impacts to the transportation infrastructure and traffic safety in the oil and gas industry area is low relative to the magnitude of the impact.” This analysis also described uneven distribution of benefits. For example, individuals and energy companies located outside of the region held 96 percent of Eagle Ford mineral wealth.¹²⁶⁴

- March 4, 2018 – Local governments in highly rural regions experiencing large-scale growth in oil and gas activity faced the greatest fiscal challenges, according to a study evaluating the effects of this development in 21 U.S. regions during boom and bust periods. “Increased crime, vehicle accidents, and other public safety issues were major challenges,” and “the scale of these challenges tended to track the scale of population growth and a region's rurality.” Though revenues from property and sales taxes and other sources resulted in a net gain for many local governments, the volatility of industry activity and population growth created especially difficult challenges for some municipalities. In a rural western Colorado city, for example, residents were faced with increased taxes, as well as increased water and wastewater fees to service the debt incurred by needed upgrades.¹²⁶⁵
- February 13, 2018 – Economists found that Oklahoma home prices in 2006 to 2014 declined by three to four percent after experiencing a moderate earthquake. Further, sale prices for the properties affected by the most intense earthquakes were estimated to have declined from 3.5-10.3 percent. The study also found that houses were on the market significantly longer following earthquake exposure. The intensity of a quake for each property was determined by linking earthquake magnitude to the distance of the home from its epicenter. The researchers wrote, “Oklahoma provides an exceptional case study as the state most affected by sudden changes in seismic frequency and intensity,” and that although the exact proportion of earthquakes induced by oil and gas activity is not certain, “the Oklahoma Geological Survey has recognized that the majority of earthquakes are likely to be induced.” They concluded that the rise in earthquake activity “has inflicted substantial costs on homeowners in Oklahoma.”¹²⁶⁶
- January 25, 2018 – In the Marcellus Shale region, counties experiencing a fracking boom suffered a 30 percent increase in violent crime, compared to those with no gas boom. Aggravated and sexual assaults were the crimes primarily responsible for this increase. This research took advantage of “natural experiment” conditions in the region, with a prohibition on fracking in New York State and a fracking boom across the border in Pennsylvania. The study used 2004 to 2012 county-level data from New York and

¹²⁶⁴ Theodori, G. L. (2018). Shale energy development in the Southern United States: A review of perceived and objective social impacts. *The Extractive Industries and Society*, 5, 610-618. doi: 10.1016/j.exis.2018.05.006

¹²⁶⁵ Newell, R. G., & Raimi, D. (2018). The fiscal impact of increased U.S. oil and gas development on local governments. *Energy Policy*, 117, 14-24. doi: 10.1016/j.enpol.2018.02.042

¹²⁶⁶ Cheung, R., Wetherell, D., & Whitaker, S. (2018). Induced earthquakes and housing markets: Evidence from Oklahoma. *Regional Science and Urban Economics*, 69, 153-166. doi: 10.1016/j.regsciurbeco.2018.01.004

Pennsylvania Marcellus Shale regions, on unconventional gas wells drilled, and on seven “FBI Index I” offenses. The offenses were violent crimes (aggravated assault, rape, robbery, and murder) and property crimes (larceny, burglary, and auto theft). While violent crimes increased in fracking boom areas, property crimes did not. The research featured many controls to isolate the effects of the fracking economy on crime rates. In addition, “victimization costs” were estimated to be \$8.1 million per year in high fracking counties. “Policymakers along with oil and natural gas proponents often cite the benefits in terms of jobs and income that are created in a community. However, the welfare costs of victims of crimes, among other issues, should also be considered to make optimal policy decisions.”¹²⁶⁷

- January 24, 2018 – The nearest full-time fire department to a deadly Quinton, Oklahoma natural gas rig explosion was nearly 30 miles away, according to an *E&E* investigation focusing on emergency response. “The deaths highlight a crucial fact of the drilling boom—much of it has occurred in rural areas where small-town police officers, sheriff’s deputies and volunteer firefighters are often the first responders.”¹²⁶⁸
- January 13, 2018 – Sex trafficking in oil boomtowns remains a huge problem, according to interviews with 185 health and social service professionals, criminal justice personnel, industry and community representatives, and victims of violence in the Bakken oil field region. These results are reflective of the growing literature on the topic. Interviewees shared information on increases in domestic violence, dating violence, sexual assault, stalking, and sex trafficking. Findings demonstrated that sex trafficking was linked to “a confluence of underlying forces including big oil money, an increase in drug cartels and drug use, degradation of women in a male-dominated workforce, increased access to weapons, and a rise in transient populations.” A noteworthy contribution of this study was the documentation that participants felt unprepared to address the needs of victims of sex trafficking, having very few resources, and limited background and experience with these problems.¹²⁶⁹
- December 12, 2017 – Fracking is unlikely to be a panacea for economically marginalized rural, suburban, or urban areas, and economic optimism regarding fracking tends to be overgeneralized, according to a study analyzing national data on socioeconomic wellbeing for the years 2000 to 2011. Researchers noted that large profits for industry and economic development “may not trickle down to residents living in high-production counties,” but instead often benefit a relative few, over a temporary time period. The study measured percentage of families below the poverty line in each county, average earnings, median household income, and employment status, to understand these socioeconomic impacts of oil and gas booms. Their literature review also uncovered a disparity in findings: “industry-funded studies have found substantial economic windfalls

related to extraction... but the peer-reviewed literature suggests mixed or modest effects.”¹²⁷⁰

- September 26, 2017 – The partial abandonment of the Eagle Ford Shale dramatically hurt small business owners, according to a report by *Bloomberg*. “As the shale drillers moved on to richer fields, the South Texas landscape became pockmarked with abandoned structures. This nimbleness—the ability to just pack up and leave at a moment’s notice—may give U.S. oil companies a competitive advantage against their more rigid state-run OPEC rivals, but there is a human cost to it all.” Concerning one tool and supply company in the region, the investigation found: “During the height of the Eagle Ford boom, R. Katz was supplying as many as 52 rigs and employing as many as 18 people in its office outside Cuero’s main strip. Today, it’s got 11 rig clients and three employees.”¹²⁷¹
- August 10, 2017 – Researchers from the independent, nonpartisan economic research group Resources for the Future studied the impacts of unconventional oil and gas booms on public school districts in the oil- and gas-producing states Pennsylvania, Ohio, West Virginia, North Dakota, Montana, and Colorado between 2000 and 2013. Using quantitative data analysis as well as extensive interviewing with parents and students in the districts, the study addressed the effects of recent oil and gas booms on student enrollment, teachers, public education finances, and student achievement metrics. Though divergent trends were found between school districts in the eastern versus western U.S., “nearly all boom districts reported heightened stress from financial volatility.” Though some districts had a statistically positive increase in per student funding while others had a decline, “the study found that greater revenues do not always translate into increased educational outcomes.... One western Colorado school district had to operate on a four-day-a-week schedule and cut academic programs because of increased economic volatility.”¹²⁷² As reported in *U.S. News and World Report*, “the boom-and-bust cycle of the industry was found to create overwhelming stress on local districts as students and teachers were moving in and out of a region to meet the economic demands of drilling.”¹²⁷³
- June 18, 2017 – A Shale Task Force of the Academy of Medicine, Engineering and Science of Texas (TAMEST) developed the report, *Environmental and Community Impacts of Shale Development in Texas*, a “first-of-its-kind, comprehensive review of scientific research and related findings regarding impacts of shale oil and gas production

in Texas.” Transportation impacts included road damage costing Texas an estimated \$1.5 to \$2 billion a year, and rural crashes involving commercial vehicles increasing over 75 percent in some drilling regions. The number of fatal collisions in the Permian Basin doubled from 94 during 2006 to 2009, to 183 from 2010 to 2013. The report also noted that Texas is the only major oil and gas producing state without a “surface damage act” to protect landowners, who do not own the mineral rights on their land and have little control over oil and gas operations. The report, which also addressed topics such as seismicity, air, and water, noted that the various impacts of oil and gas development “can’t be studied or addressed in isolation.” Authors continued, “[t]hese connections are important and pervasive, but are not well-studied yet.” TAMEST includes all of the state’s Nobel Laureates, plus Texas-based members of the National Academies of Sciences, Engineering, and Medicine.¹²⁷⁴

- April 6, 2017 – The economic impacts of fracking at the advent of the Marcellus Shale boom is an understudied topic. The onset of fracking was so rapid that academics were challenged to provide accurate and timely information to policymakers, and the one major paper that did appear in 2011 did not clearly disclose its industry sponsorship. A Pennsylvania Department of Community & Economic Development-funded study set out to investigate those early years. In addition to scrutinizing available data, the authors conducted a survey of 1,000 landowners in Bradford and Tioga counties, the two counties with the most fracked wells in Pennsylvania at the start of the boom. From the 501 returned surveys, they determined residents saved more than half of their earliest royalty and lease income, which “may or may not ultimately be spent within Pennsylvania.” Hence, the windfalls from mineral rights created “little economic impact during the year received.” Further, the study’s overall “lower-bound” estimate of economic impacts for 2009 found that fully 15.4 percent of these mineral rights were owned by non-residents. At the same time, survey results showed that 37 percent of the workforce consisted of non-residents with only half of their income staying in the state. This study’s upper-bound jobs count for 2009 was substantially lower than the estimates that made at the time. In addition, the study urged caution regarding future jobs predictions, as the sharp decline between 2011 and 2013 “was totally unexpected” and was not captured in a 2010 forecast for jobs in 2020.¹²⁷⁵
- April 5, 2017 – Economists at Colorado State University quantified the “substantial environmental costs associated with hydraulic fracturing,” as part of an analysis of the market and non-market costs and benefits of fracking in 14 U.S. states. These costs were “dominated by \$27.2 billion (\$12.5–\$41.95 billion) health damages from air pollution.” They also found costs including “\$3.8 billion (\$1.15–\$5.89 billion) in greenhouse gas emissions, \$4 billion (\$3.5–\$4.45 billion) in wildlife habitat fragmentation, and \$1 billion (\$0.5–\$1.6 billion) in pollution of private drinking water wells.” Results also showed a disconnect between those reaping economic rewards from fracking and those paying the

doi: 10.25238/TAMESTstf.6.2017

¹²⁷⁵ Hoy, K. A., Kelsey, T. W., & Shields, M. (2017). An economic impact report of shale gas extraction in Pennsylvania with stricter assumptions. *Ecological Economics*, 138, 178-185. doi: 10.1016/j.ecolecon.2017.03.037

price: the “benefits” (mostly in the form of lower natural gas prices to residential, commercial, and industrial consumers) were geographically dispersed while the costs tended to concentrate in localized areas where drilling took place. Although the most comprehensive economic study to date, this analysis was not able to fully quantify all costs, including those related to water contamination (beyond surface-spill related costs for damage to private wells); diminishment of open spaces and aesthetics for community members; and seismic activity. The authors concluded that costs might well outweigh the benefits for suburban dwellers near fracking operations, as exemplified by Denton, Texas, where “nearly all the royalty money was flowing to mineral owners living elsewhere...rather than to adjacent homeowners.”¹²⁷⁶

- February 19, 2017 – The *New York Times* reported on the oil and gas industry’s embrace of automation and its threat to preserving and bringing back jobs. Executives interviewed as part of the investigation were straightforward in their intentions to shrink their work forces. “‘We want to transform our work force to the point where we need to hire fewer people,’ said Joey Hall, Pioneer’s executive vice president for Permian Operations.” In 2016 Pioneer Natural Resources added 240 wells in West Texas without adding any new employees. A vice president at a Pennsylvania manufacturer of drilling rigs stated, “If it’s a repetitive task, it can be automated, and I don’t need someone to do that. I can get a computer to do that.”¹²⁷⁷
- February 1, 2017 – Stanford University earth science professor Robert Jackson and two professors of law assessed how a new type of “conservation easement,” an established kind of legal agreement, could enable landowners to restrict fracking on their properties. A mineral estate conservation easement (MECE) can serve as a private landowner response to the demonstrable threats of fracking to property and community: “Accompanying the rise of high-volume hydraulic fracturing has been a suite of environmental and social concerns, including potential water and air contamination, greenhouse gas emissions, health effects, and community disruptions.” “We support the exploration of MECEs as an additional tool for landowners to exercise their rights and responsibilities,” the team concluded.¹²⁷⁸
- January 26, 2017 – Automation is reducing the size of drilling crews and will lessen the number of jobs added nationally with any upturn in oil and gas operations, according to a piece on OilPrice.com. The author described predictions, including:

¹²⁷⁶ Loomis, J., & Haefele, M. (2017). Quantifying market and non-market benefits and costs of hydraulic fracturing in the United States: A summary of the literature. *Ecological Economics*, 138, 160-167. doi: 10.1016/j.ecolecon.2017.03.036

Automated drilling rigs may be able in the future to reduce the number of persons in a drilling crew by almost 40 percent, from 25 workers to 15 workers, *Houston Chronicle's* Jordan Blum writes, quoting industry analysts.

Drilling company Nabors Industries expects that it may be able to reduce the size of the crew at each well site to around 5 people from 20 workers now if more automated drilling rigs are used, Bloomberg's David Wethe says.¹²⁷⁹

- December 22, 2016 – Researchers with the Energy Policy Institute at the University of Chicago measured the costs and benefits of fracking in local communities across nine U.S. shale basins. They found that, despite contributions to local economies with the arrival of fracking, residents experienced decreases in local quality of life. Spikes in crime were the most directly measurable of these effects. “Despite local governments’ efforts to improve public safety—allocating 20 percent more funding—the crime rates still marginally increased.” The study also found unequal distribution of benefits. Students, the elderly, and those who don’t own mineral rights did not benefit at all. Their analysis found an average gain of about \$1,300 to \$1,900 per household per year, but these gains were offset by a reduction in the typical household’s quality of life, which the authors computed at about \$1,000 to \$1,600 per year.¹²⁸⁰
- December 21, 2016 – Economists from the University of Anchorage and Montana State University studied the impact of regional shale energy booms on crime rates across U.S. counties from 2000 to 2013, documenting increased rates of many types of crime, including assault, rape, larceny, and auto theft. In 2013, they pegged the average monetary cost of these additional crimes at \$2 million per county. Researchers emphasized these results represented short-term costs only, as they could not predict how crimes rates and attendant costs will accrue over longer periods of time, as, for example, if criminal behavior and labor migration facilitate a slow drain of human and physical capital from the region and propagate “a long-term resource curse.” The study also found “that registered sex offenders moved in disproportionate numbers to boom towns in North Dakota,” and “that income inequality increased as the shale boom progressed.”¹²⁸¹
- May 24, 2016 – In 327 U.S. counties previously at the center of the fracking boom, overdue car loans approached their highest level in five years, and late mortgage payments also rose, according to a report by the *Financial Times* that examined data from the Federal Reserve Bank of New York. These trends stood in stark contrast to lowered overdue debt rates in the rest of the U.S. This surge in late car payments in intensely fracked areas of the United States has “exposed the damage done by the collapse in

¹²⁷⁹ Paraskova, T. (2017, January 26). Robots over roughnecks: Next drilling boom might not add many jobs. *OilPrice.com*. Retrieved from <https://oilprice.com/Energy/General/Robots-Over-Roughnecks-Next-Drilling-Boom-Might-Not-Add-Many-Jobs.html>

drilling activity and marred broadly positive trends for late debt payments by American consumers.”¹²⁸²

- May 8, 2016 – With the downturn in the fracking industry, Wisconsin’s sand mining sector, which provides silica sand for fracking operations, has also slumped and prompted significant layoffs and job losses in both 2015 and 2016, according to a report by Eau Claire’s *Leader-Telegram*. “This is what the bust part of the boom-and-bust cycle of the energy sector looks like, and it’s something west-central Wisconsin residents, who are mostly new to the industry, aren’t used to seeing.” Other companies that supply goods and services to sand mining operations in the region have also experienced a downturn.¹²⁸³
- March 8, 2016 – A DeWitt County, Texas judge estimated it will cost his county \$432 million to rebuild its roads, noting that if a road “leads to a rig site, it’s bound to be a broken road.” The judge stated that ultimately the companies would pay a large share.¹²⁸⁴
- February 22, 2016 – *Inside Energy* investigated oil-industry related wage theft claims in the West, finding “a growing number of oil workers are turning to the courts, saying they weren’t paid fairly even when times were good.” Between 2010 and 2015, wage theft suits against oil and gas companies in Colorado increased by a factor of nine, and in Texas nearly ten times. The investigation found that oil and gas companies were consistently among the top violators of wage laws—especially in failure to pay overtime. A federal investigation of the industry led to the recovery of \$40 million dollars in unpaid wages. One of the officers involved in the investigations is quoted saying, “We have found cases where workers were not even paid the minimum wage, because they’re working so many hours.... So the idea that they’re being highly compensated, in some cases, they’re not.”¹²⁸⁵
- January 13, 2016 – A fire on a fracking site in Grady County, Oklahoma that consumed 22 oil tankers required the response of six regional fire departments.¹²⁸⁶
- December 15, 2015 – The value of homes that rely on well water in Pennsylvania dropped an average of \$30,167 when fracking took place within 1.5 kilometers, according to a study by Duke University researchers published in the *American Economic Review*. For these groundwater-dependent homes, a fracking well located within one kilometer was linked to a 13.9 percent average decrease in values; homes with wells at

least two kilometers away maintained their value. The study was based on home sales between 1995 and 2012 in 36 counties. Researchers stated that their figures may not fully reflect the total costs associated with groundwater contamination risk, as, for example, when homeowners purchase expensive home water filtration systems. Though their study does not incorporate data on actual contamination, concerns about contamination can significantly affect property values. Researchers found “strong evidence of localized costs borne particularly by groundwater-dependent homes.”¹²⁸⁷

- December 8, 2015 – Even as housing prices in shale gas-areas of Pennsylvania have dropped along with fracking activity, many seniors and people living on low incomes are still being priced out of the market, *StateImpact* reported. Pennsylvania still lacks a quarter million affordable rental homes for people in poverty despite a 2012 law requiring gas companies to pay well fees intended to offset the costs of affordable housing programs in communities where drilling is occurring.¹²⁸⁸
- December 2, 2015 – “The local economy is feeling the pinch” of the downturn of activity in Pennsylvania’s gas fields, according to a Reuters report. The late 2015 slump marked a turning point in Marcellus Shale fracking. Regional economic effects reported include empty hotel rooms and foreclosure notices in Lycoming County at their highest since data were first collected.¹²⁸⁹
- October 7, 2015 – Vehicular collisions and Texas fracking activity are closely linked, according to a report by the Texas A&M University Transportation Institute. Researchers analyzed the number of crashes and injuries across Texas during the period from 2006 to 2009, when drilling and fracking operations were intensive over the Barnett Shale, as well as from 2010 to 2013, when activity increased in the Permian Basin in West Texas and the Eagle Ford Shale in South Texas, and decreased in the Barnett. Collisions increased where shale gas activity increased and decreased where it slowed down.¹²⁹⁰ Quoted in the *Texas Tribune*, report co-author Cesar Quiroga said, “The two trends correlated so well, and they were perfectly aligned . . . We could use this as a predictive model.”¹²⁹¹ Further, the increase was greater in South Texas, the region that relies most heavily on horizontal, hydraulic fracking requiring millions of gallons of water and sand to be trucked in, compared to West Texas which does use fracking but also more simple, vertical wells. The comprehensive cost of these collisions was estimated to be about \$2

billion more from 2010 to 2013—in both the Eagle Ford and Permian Basin—compared to the previous period.

- September 30, 2015 – The North Dakota Bureau of Criminal Investigation was set to hire nine new agents, reported the *Billings Gazette*, “...allowing for more attention to cases of human trafficking and organized crime in western North Dakota ... as increased oil production resulted in growing populations.”¹²⁹²
- September 29, 2015 – “New residential units sit empty as gas production falls,” *HousingWire Magazine* wrote, following up on their earlier reporting describing the link between the drilling boom and the real estate boom in the Bakken shale region of North Dakota. Economic data indicate that Bakken drilling is not lasting long enough to sustain the building explosion.¹²⁹³
- September 9, 2015 – Most local governments in Western North Dakota and Eastern Montana’s Bakken region have experienced net negative fiscal effects, according to a Duke University analysis published by the National Bureau of Economic Research. These trends were also seen in municipalities in rural Colorado and Wyoming, which also struggled to manage fiscal impacts during recent oil and gas booms, but in these two states the fiscal impact eased as drilling activity slowed.¹²⁹⁴ Referencing the report, *McClatchyDC* wrote, “North Dakota cities and counties have been slammed.” Municipal challenges have included providing water and sewer infrastructure, substantial damage to roads, soaring housing prices, and strained emergency services.¹²⁹⁵
- August 27, 2015 – Fracking in or near public parks could cause tourists to stay away and lead to a decline in park use, according to a report published by a team of tourism, recreation, and sport management researchers from the University of Florida, North Carolina State University, and Florida State University. Using data collected from 225 self-identified park users from Pennsylvania, Ohio, West Virginia, Kentucky, and Tennessee, researchers reported that only one-third of participants were willing to participate in recreational activities near fracking operations, compared to 38 percent unwilling, and 29 percent neutral. Forty-six percent of respondents supported a ban on fracking on public lands, while 20 percent agreed with promoting fracking on public lands.¹²⁹⁶

- July 1, 2015 – Britain’s Department for Environment, Food & Rural Affairs released previously redacted sections of a report on the impacts of drilling and fracking. The report found that housing prices near fracking wells would likely fall up to seven percent for houses within a mile of wells. Furthermore, properties within one to five miles of fracking sites could incur additional insurance costs. The report warned of environmental damages, including from leakage of fracking waste fluids, and found that public health could be affected indirectly through consumption of contaminated wildlife, livestock, or agricultural products. The report also found potential for some benefits, such as job growth.¹²⁹⁷
- July 2015 – A working paper by researchers with the National Bureau of Economic Research found that fracking resulted in an increase in male teen high school dropout rates. “Our estimates imply that, absent fracking, the male-female gap in high school dropout rates among 17- 18-year olds would have narrowed by about 11 percent between 2000 and 2013 instead of remaining unchanged.” The authors explained that by increasing the demand for low-skilled labor, fracking could slow growth in educational attainment. They noted that the relative wage boost from fracking may be only temporary. Indeed, by the end of the sample period, the benefits had started to wane as the labor demand from fracking appeared to no longer favor dropouts. Thus, the fracking boom may be inhibiting educational achievement among young men who “would already be near the bottom of the skill distribution, with possible implications for future productivity and the social safety net.”^{1298, 1299}
- March 20, 2015 – The U.S. Attorney for Western New York linked a rise in production of methamphetamine to use among workers in the fracking fields of northern and western Pennsylvania. Surging demand for the drug, which allows users to stay awake for 48 to 72 hours, may be related to the extremely long working hours that employees in the gas industry must endure.¹³⁰⁰
- January 4, 2015 – A documentary by Forum News Service, “Trafficked Report,” revealed that sex trafficking, including of children, in the Bakken oil fields of North Dakota was a significant problem.¹³⁰¹ The dynamics of the oil boom, with an influx of out-of-state and

primarily male workers far from their families, created an increase in demand for prostitution.¹³⁰²

- December 28, 2014 – The *New York Times* profiled the impacts of oil drilling and fracking on the Fort Berthold Indian Reservation in North Dakota, finding corruption, crime, and negative environmental impacts. Aside from a significant rise in jobs, which often go to transient workers, many residents “see deterioration rather than improvement in their standard of living. They endure intense truck traffic, degraded roads, increased crime, strained services and the pollution from spills, flares and illegal dumping.” According to the *Times*' calculation, the reservation had seen 850 oil-related environmental incidents from 2007 through mid-October 2014, which generally went unpunished.¹³⁰³
- December 26, 2014 – Examining Pennsylvania Department of Transportation data, Ohio's *Star Beacon* newspaper found that fracking poses a safety threat on rural roads. The paper found that Pennsylvania's five busiest drilling counties recorded 123 more heavy truck crashes in 2011 than before the gas boom began—a 107 percent increase. The paper noted the burden drilling and fracking placed on local communities and governments, including the strain on local emergency responders.¹³⁰⁴
- December 17, 2014 – Heavy drilling and fracking (defined as 400 or more wells drilled within a county over 5-8 years) was positively correlated with increased crime, sexually transmitted diseases, and traffic fatalities, according to a report by the Multi-State Shale Research Collaborative.¹³⁰⁵ The report looked at the impacts in Pennsylvania, Ohio, and West Virginia, primarily finding statistically significant impacts in six heavily drilled counties in Pennsylvania. In those six counties, violent crime increased 17.7 percent—corresponding to about 130 more violent crimes in those counties in 2012—compared to a decrease in violent crime rates in both urban and rural non-drilling communities. Property crime increased 10.8 percent in those six counties, drug abuse rates rose 48 percent, and drunk-driving offenses rose 65 percent compared to 42 percent in rural areas with no drilling. The report found a statistically significant increase of 24 percent to 27 percent in rates of sexually transmitted diseases across drilling counties in all three states. Motor vehicle fatalities increased 27.8 percent in Pennsylvania's six high-drilling

counties. The report found a modest increase in jobs, but noted that an influx of out-of-state workers at least partially explained the increases in traffic and crime.¹³⁰⁶

- December 15, 2014 – A report written in French by Quebec’s Advisory Office of Environmental Hearings concluded that the environmental costs of fracking in the St. Lawrence Lowlands would outweigh the potential economic benefits. In a press release, the Advisory Office of Environmental Hearings concluded that fracking “would not be advantageous for Quebec because of the magnitude of the potential costs and externalities, compared to royalties that would be collected by Quebec. Other concerns also remain, including plans of social acceptability, legislation, and a lack of knowledge, particularly with respect to water resources.”¹³⁰⁷
- October 30, 2014 – The *New York Times* profiled the profound impact heavy drilling has had on Glasscock County, Texas, including its farming community. Farmers described increases in trash, traffic accidents, clashes around farmers selling groundwater to drillers, and economic detriment. In many cases, acres of farmland around a drill site “will probably never be suitable for fertile farming again,” and farmers are “at the mercy” of what drillers want to pay for damages. The county itself receives revenue, but most of that additional money “is being used to repair roads damaged by oil field truck activity. Overall, the gains from drilling are not viewed as worth the drawbacks in a county long dominated by cotton farming.”¹³⁰⁸
- September 28, 2014 – A *Washington Post* investigation reported on heroin and methamphetamine addiction—and associated violent crime—among Native American communities located within the Bakken Shale oil fields. According to a chief judge for the Mandan, Hidatsa, and Arikara Nation, “The drug problem that the oil boom has brought is destroying our reservation.”¹³⁰⁹
- September 11, 2014 – An editor for the *Washington Post* examined jobs and manufacturing data in Youngstown, Ohio, to demonstrate that drilling and fracking are not resulting in a revitalization of the Rust Belt as some proponents and a prominent *New York Times* story asserted. The *Post* determined that in Youngstown, Ohio, the manufacturing sector has lost jobs by the tens of thousands in the last twenty years and the oil and gas industry has created approximately two thousand jobs since the recession

ended. Six years prior, there were 13,000 more jobs in the Youngstown metro area than there were in summer 2014.¹³¹⁰

- September 9, 2014 – A study by researchers at Colorado State University examined the political economy of harm and crime associated with the oil and gas industry in rural Colorado, particularly around the rise of fracking. The researchers looked at complaints that citizens filed with the state, and also conducted interviews and examined other data. They found 2,444 complaints between November 2001 and June 2013 covering a range of issues including water, environment, noise, air quality, land use, and more. They characterized citizen complaints as “extensive and complex” and concluded that, regardless of the nature of the harm, most were “persistent and omnipresent” rather than short-lived, isolated problems.¹³¹¹
- September 6, 2014 – In Williams County, North Dakota, in the Bakken Shale, increases in crime have corresponded with the flow of oil. The infusion of cash has attracted career criminals who deal in drugs, violence, and human sex trafficking. The *Williston Herald* portrayed, in a “reader’s discretion advised” article, the rapid rise of “index crimes”—“violent crimes that result in the immediate loss of an individual’s property, health or safety, such as murder, larceny and rape.” With fewer than 100 law enforcement personnel, crime in Williams County “has risen in kind with the county’s population, but funding, staffing and support training for law enforcement has not.”¹³¹²
- September 2014 – Reporting on the social, environmental, health and safety, and economic burdens endured by localities from fracking, the magazine *Governing: The States and Localities* found that “fracking, in many cases, negatively impacts property values, which in turn depresses property tax revenue. For property owners who own the rights to the oil and gas on their land, the effects of drilling can be offset by royalty payments. But localities have no revenue offset if properties lose value.”¹³¹³
- August 26, 2014 – The U.S. Justice Department Office on Violence Against Women awarded three million dollars to five rural and tribal communities to prosecute crimes of violence against women and provide services to victims of sexual assault, domestic violence, and stalking in the Bakken Region of North Dakota and Montana.¹³¹⁴ Rationale documented by tribal leaders, law enforcement, and the FBI included, “rapid

development of trailer parks and modular housing developments often referred to as ‘man camps;’ abrupt increase in cost of living, especially housing; rapid influx of people, including transients, in a previously rural and stable community; constant fear and perception of danger; and a lost way of life. Local and tribal officials and service providers reported that these changes have been accompanied by a rise in crime, including domestic and sexual violence.”¹³¹⁵

- May 27, 2014 – A *Bloomberg News* analysis of 61 shale-drilling companies found that the economic picture of shale oil and gas is unstable. Shale debt has almost doubled over the last four years while revenue has gained just 5.6 percent. For the 61 companies in their analysis, *Bloomberg News* reported: “In a measure of the shale industry’s financial burden, debt hit \$163.6 billion in the first quarter.” Further, *Bloomberg* noted that drillers are caught in a bind because they must keep borrowing to pay for exploration needed to “offset steep production declines typical of shale wells.... For companies that can’t afford to keep drilling, less oil coming out means less money coming in, accelerating the financial tailspin.”¹³¹⁶
- May 5, 2014 – An Associated Press analysis found that traffic fatalities have spiked in heavily drilled areas of six states, whereas most other roads in the nation have become safer even as population has grown. In North Dakota drilling counties, for instance, traffic fatalities have increased 350 percent.¹³¹⁷
- April 16, 2014 – A comprehensive article in the *Albany Law Review* concluded that the risks inherent with fracking are not covered by homeowner’s insurance, not fully insured by the oil and gas industry, and threaten mortgages and property value.¹³¹⁸
- April 2014 – A report by the Multi-State Shale Research Collaborative, “Assessing the Impacts of Shale Drilling: Four Community Case Studies,” documented economic, community, government, and human services impact of fracking on four rural communities. The study found that fracking led to a rapid influx of out-of-state workers and, although some new jobs were created, these were accompanied by additional costs for police, emergency services, road damage, and social services. In addition, increased rents, and a shortage of affordable housing accompanied the fracking boom.

Unemployment rose after one county's boom ended; in another county, unemployment stayed above the state average throughout.¹³¹⁹

- March 27, 2014 – A report by researchers at Rand Corporation determined that each shale gas well in Pennsylvania causes between \$5,400 and \$10,000 in damage to state roads. The report did not calculate damage to local roads, which is also significant. Researchers used estimates of truck trips that are significantly below the number estimated for New York by the New York State Department of Environmental Conservation (NYS DEC).^{1320, 1321}
- February 15, 2014 – The *Los Angeles Times* detailed steep increases in crime that have accompanied fracking in parts of the Eagle Ford Shale in Texas, including sexual assaults and thefts.¹³²²
- February 14, 2014 – Pennsylvania landowners with fracking leases rallied in Bradford County against gas companies for precipitous drops in royalty payments.¹³²³
- December 20, 2013 – The National Association of Realtors' *RealtorMag* summarized a growing body of research, including a University of Denver survey and a *Reuters* analysis, that shows threats property values from fracking and gas drilling.¹³²⁴
- December 12, 2013 – A *Reuters* analysis discussed how oil and gas drilling has made making some properties “unsellable” and researched the link between drilling and property value declines. The analysis highlighted a Duke University working paper that finds shale gas drilling near homes can decrease property values by an average of 16.7 percent if the house depends on well water.¹³²⁵

- December 10, 2013 – Pennsylvania’s *Daily Review* reported that more gas companies are shifting costs to leaseholders and that royalty payments are drastically shrinking. The story quoted Bradford County Commissioner Doug McLinko saying that some gas companies “are robbing our landowners” and that the problem of royalty payments being significantly reduced by deductions for post-production costs “is widespread throughout our county.”¹³²⁶
- November 30, 2013 – The *New York Times* reported striking increases in crime in Montana and North Dakota where the oil and gas boom is prevalent, as well as challenges faced by local residents from the influx of out-of-area workers and the accompanying costs. The *New York Times* reported, “‘It just feels like the modern-day Wild West,’ said Sgt. Kylan Klauzer, an investigator in Dickinson, in western North Dakota. The Dickinson police handled 41 violent crimes last year, up from seven only five years ago.”¹³²⁷
- November 21, 2013 – The Multi-State Shale Research Collaborative released a six-state collaborative report demonstrating that the oil and gas industry has greatly exaggerated the number of jobs created by drilling and fracking in shale formations. The report found that far from the industry’s claims of 31 direct jobs created per well, only four jobs are created for each well. It also demonstrated that almost all of the hundreds of thousands of ‘ancillary’ jobs that the drilling industry claims are related to shale drilling existed before such drilling occurred. As Frank Mauro, Executive Director Emeritus of the Fiscal Policy Institute put it, “Industry supporters have exaggerated the jobs impact in order to minimize or avoid altogether taxation, regulation, and even careful examination of shale drilling.”¹³²⁸
- November 12, 2013 – *The American Banker* reported that the “Fracking Boom Gives Banks Mortgage Headaches,” with a number of financial institutions refusing to make mortgages on land where oil and gas rights have been sold to an energy company. The article stated that the uniform New York state mortgage agreement used by Fannie Mae and Freddie Mac requires that homeowners not permit any hazardous materials to be used or located on their property. Fracking is therefore a problem because it is just such a hazardous activity with use of hazardous materials.¹³²⁹
- September 25, 2013 – A report found that fracking is linked to significant road damage, increased truck traffic, crime, and strain on municipal and social services. Data from the

damage. Commissioner Pawlowski reported that 56 percent of 194 trucks checked were over the legal weight limit and 50 percent were also cited for safety violations.¹³³⁷

- May 4, 2013 – Pennsylvania’s *Beaver County Times* asked, “What boom?” in pointing to Keystone Research Center data showing that the number of jobs numbers created by shale gas extraction do not add up to what the gas industry claims, noting that unemployment has increased and the state actually fell to 49th in the nation for job creation.¹³³⁸
- April 2, 2013 – The *New York Times* reported that manufacturing jobs resulting from an abundance of shale gas have not appeared. “The promised job gains, other than in the petrochemical industry, have been slow to materialize,” The *New York Times* reported. The article suggested that increased automation has made it unlikely that manufacturers will add many jobs.¹³³⁹
- March 19, 2013 – The *Wall Street Journal* reported that the shale gas boom has not had a big impact on U.S. manufacturing because lower energy prices are only one factor in a company’s decision on where to locate factories, and not always the most important factor. “Cheap energy flowing from the U.S. shale-gas boom is often touted as a ‘game changer’ for manufacturing,” the *Journal* reported. “Despite the benefits of lower energy costs, however, the game hasn’t changed for most American manufacturers.”¹³⁴⁰
- February 2013 – A peer-reviewed analysis of industry-funded and independent studies on the economics of fracking found that it is unlikely that fracking will lead to long-term economic prosperity for communities. The analysis noted that shale gas development brings a number of negative externalities including the potential for water, air, and land contamination; negative impacts on public health; wear and tear on roads and other infrastructure; and costs to communities due to increased demand for services such as police, fire departments, emergency responders, and hospitals.¹³⁴¹

- November 16, 2012 – A Duke University study showed a drop in home values near fracking for properties that rely on groundwater.¹³⁴²
- September 27, 2012 – The *New York Times* reported that the prospect of fracking has hindered home sales in the Catskills and raised concerns about drops in property values, according to real estate agents and would-be buyers.¹³⁴³
- August 17, 2012 – A study by the state agencies, the Montana All Threat Intelligence Center and the North Dakota State and Local Intelligence Center, found that crime rose by 32 percent since 2005 in communities at the center of the oil and gas boom.¹³⁴⁴
- October 30, 2011 – A comprehensive article in the *New York State Bar Association Journal* concluded that the risks inherent with fracking threaten mortgages.¹³⁴⁵
- October 26, 2011 – The Associated Press reported that areas with significant fracking activity, including Pennsylvania, Wyoming North Dakota and Texas, are “seeing a sharp increase in drunken driving, bar fights and other hell-raising.”¹³⁴⁶
- October 19, 2011 – A *New York Times* investigation found that fracking can create conflicts with mortgages, and that “bankers are concerned because many leases allow drillers to operate in ways that violate rules in landowners’ mortgages,” and further that “[f]earful of just such a possibility, some banks have become reluctant to grant mortgages on properties leased for gas drilling. At least eight local or national banks do not typically issue mortgages on such properties, lenders say.”¹³⁴⁷
- September 7, 2011 – The NYS DEC estimated that 77 percent of the workforce on initial shale gas drilling projects would consist of transient workers from out of state. Not until the thirtieth year of shale gas development would 90 percent of the workforce be comprised of New York residents.¹³⁴⁸

- August 15, 2011 – The *Pittsburgh Post-Gazette* reported that increases in crime followed the Pennsylvania gas drilling boom, noting, for instance, that drunken driving arrests in Bradford County were up 60 percent, DUI arrests were up 50 percent in Towanda, and criminal sentencing was up 35 percent in 2010.¹³⁴⁹
- July 26, 2011 – A New York State Department of Transportation document estimated that fracking in New York could result in the need for road repairs and reconstruction costing \$211 million to \$378 million each year.¹³⁵⁰
- June 20, 2011 – A Keystone Research Center study found that the gas industry’s claim of 48,000 jobs created between 2007 and 2010 as a result of natural gas drilling in Pennsylvania is a far cry from the actual number of only 5,669 jobs—many of which were out-of-state hires.¹³⁵¹
- May 9, 2011 – A study in the *Journal of Town & City Management* found that shale gas development can impose “significant short- and long-term costs” to local communities. The study noted that shale gas development creates a wide range of potential environmental hazards and stressors, all of which can adversely impact regional economies, including tourism and agriculture sectors.¹³⁵²
- November 30, 2010 – The *Dallas Morning News* featured a story, “Drilling Can Dig into Land Value,” reporting that the Wise County Central Appraisal District Appraisal Review Board found that a drilling company had caused an “extraordinary reduction” in property value, by 75 percent.¹³⁵³
- November 28, 2010 – The Texas *Wise County Messenger* reported that some landowners near fracking operations experience excessive noise, exposure to diesel fumes, and problems with trespassing by workers.¹³⁵⁴

Inflated estimates of oil and gas reserves and profitability

Industry projections of oil and gas reserves and profitability of drilling have proven undependable. Over time, well production has become increasingly short-lived, which has led companies drilling shale to reduce the value of their assets by billions of dollars, creating shortfalls that are largely filled through asset sales and mounting debt load. Throughout the ten-year fracking boom, the industry as a whole has spent more money drilling wells than selling oil and gas. Beginning in 2014, a fall in oil and gas prices led to a two-year downturn in fracking operations. As interest payments consumed the revenue of many smaller companies, more than 70 U.S. oil and gas companies declared bankruptcy, and the number of oil and gas rigs declined by 75 percent or more. When companies abandoned operations, they also abandoned the wells they drilled, raising questions about who serves as the custodian of inactive wells and their associated infrastructure, now and hereafter.

Beginning in 2017, a modest recovery in prices brought renewed industry enthusiasm for fracking. However, because of the rapid depletion of individual shale wells and the falling output of major shale basins, including the Bakken and the Marcellus, operators must reinvest profits to drill new wells at an increasingly rapid pace just to maintain the same level of extraction. More than half of all U.S. oil is now produced by wells that are two years old or younger, and they are pumping less oil than forecast. In the first half of 2018, despite rising oil prices, fracking-focused companies continued to lose cash.

The need to stabilize economic fundamentals by increasing production and lower costs is contributing to the shift toward “mega-fracking,” with ever-longer laterals to allow one well to access more oil or gas—and with requirements for higher volumes of water, sand, and chemicals per well.

- January 2, 2019 – An analysis by the *Wall Street Journal* comparing productivity estimates provided to investors with third-party projections revealed that thousands of shale wells are pumping considerably less oil and gas than owners were forecasting. Two-thirds of projections made by fracking companies between 2014-2017 in Texas and North Dakota oil basins were overly optimistic. All together, these companies are on track to extract 10 percent less oil and gas than they predicted. “The Journal’s findings suggest current production levels may be hard to sustain without greater spending because operators will have to drill more wells to meet growth targets.”¹³⁵⁵
- October 17, 2018 – A research brief jointly published by the Institute for Energy Economics and Financial Analysis and the Sightline Institute tracked cash flow for 33 leading fracking companies. It found that fracking-focused companies continued to lose cash through the first half of 2018. Specifically, between January and June 2018, in spite

¹³⁵⁵ Olson, B., Elliott, R., & Matthews, C. M. (2019, January 2). Fracking’s secret problem—oil wells aren’t producing as much as forecast. *Wall Street Journal*. Retrieved from <https://www.wsj.com/articles/frackings-secret-problemoil-wells-arent-producing-as-much-as-forecast-11546450162>

of rising oil prices, fracking companies spent \$3.9 billion more on drilling than they generated by selling oil and gas.¹³⁵⁶

- September 20, 2018 – Confronted with falling prices and mounting debt, Southwest Energy sold off its assets in Arkansas’ Fayetteville Shale, placing fracking on hold.¹³⁵⁷
- June 4, 2018 – A macroeconomic study using a simulation model found that economies that depend on fossil fuel extraction could be gravely harmed if global demand for fossil fuels declines in the face of innovations in energy efficiency and renewable technologies and public policy that promotes them. “Russia, the United States or Canada... could see their fossil fuel industries nearly shut down. ... The United States is worse off if it continues to promote fossil fuel production and consumption than if it moves away from them. This is due to the way global fossil fuel prices are formed. If the rest of the world reduces fossil fuel consumption and there is a sell-out, then lower fuel prices will make much US production non-viable, regardless of its own policy, meaning that its assets become stranded.”¹³⁵⁸
- June 16, 2017 – Because of a persistent slump in gas prices and the declining productivity of many of its Marcellus Shale wells, the revenue from gas drilling fees fell for a third straight year in Pennsylvania. The annual fee revenue goes to county and municipal governments, roadway repairs, and infrastructure upgrades, among other things.¹³⁵⁹
- April 3, 2017 – A British team of researchers assessed the physical footprint of well pads in Europe and the United Kingdom if shale gas development goes forward. When they included proposed setbacks for the UK—the minimal distance well pads have to be away from existing homes and other infrastructure—they found that recoverable oil and gas would be limited by 74 percent.¹³⁶⁰
- March 25, 2017 – The *Economist* took shale fracking to task for its unstable finances and inability to turn a profit. “Shale firms are on an unparalleled money-losing streak. About \$11bn was torched in the last quarter, as capital expenditures exceeded cashflows. The

cash-burn rate may well rise again this year. . . . The oil bulls of Houston have yet to prove that they can pump oil and create value at the same time.”¹³⁶¹

- March 21, 2017 – An MIT study questioned the U.S. Energy Information Administration’s rosy projections on the abundance and availability of shale gas and oil. Analyzing field data on oil wells in North Dakota’s Williston Basin, the authors found that advances in fracking technology, such as the shift to longer laterals per well, have had a more modest impact on boosting oil and gas production than the agency had estimated. At the same time, the attraction of operators to the most productive areas of basins has had a greater impact. As time goes by, the prime drilling spots with the easy-to-extract oil or gas will get used up, the authors argued, and technology may not be able to compensate.^{1362, 1363}
- July 7, 2016 – “Oil-field-services companies are depleted after slashing prices and laying off workers, and their slow recovery could crimp the energy industry’s overall ability to bounce back from the oil bust,” according to the *Wall Street Journal*. Almost 70 percent of fracking equipment in the United States has been idled, and 60 percent of field workers involved in fracking have been laid off. Halliburton alone has laid off over 28,500 workers, which is one third of its workforce. More than 70 oilfield services companies have filed for bankruptcy since the beginning of 2015.¹³⁶⁴
- June 15, 2016 – Billions of dollars of proven reserves have become unproven this year, as “59 U.S. oil and gas companies deleted the equivalent of 9.2 billion barrels, more than 20 percent of their inventories,” according to *Bloomberg*. In 2009, the Securities and Exchange Commission (SEC) made it easier for the companies to include in their proven reserves undeveloped acreage and wells that wouldn’t be drilled for years on the grounds that “shale prospects are predictable across wide expanses.” Since then, the SEC has become more strict about inflated reserves estimates.¹³⁶⁵
- May 16, 2016 – *CNN Money* reported on the two latest U.S. oil and gas bankruptcies: SandRidge Energy’s Chapter 11 filing was based on roughly \$4 billion of debt and came the week after the biggest such bankruptcy to date—that of Linn Energy with more than \$10 billion in debt. There had been at least 29 U.S. oil and gas bankruptcies in 2016 at the date of the article’s publication, bringing the 2015-2016 total to at least 64. “The industry has historically been full of wildcatters and speculators. It’s not surprising we’re

going through this boom-and-bust cycle,” the article quoted the managing director at oil restructuring firm SOLIC Capital, George Koutsonicolis, as saying.¹³⁶⁶

- May 9, 2016 – “The pace of oil patch bankruptcies is picking up,” a *Forbes* piece read, listing the 15 biggest such bankruptcies to date. “All told, 69 oil and gas producers with \$34.3 billion in cumulative secured and unsecured debt have gone under.”¹³⁶⁷
- March 25, 2016 – Oil and gas borrowers “feasted on what Bloomberg estimates was \$237 billion of easy money without scrutinizing whether the loans could endure a drastic downturn,” according to a *Washington Post* piece focusing on one company, Swift Energy, which itself was \$1.349 billion in debt and had entered bankruptcy. Despite having been cautious prior to the Texas fracking boom, “[a]s the company began to frack more often, the amount it spent on exploration and drilling skyrocketed by hundreds of millions of dollars.” Those expenses combined with global developments led to its failure, along with over 40 other oil and gas companies in 2015. “The consequences are far-reaching. The U.S. oil industry, having grown into a giant on par with Saudi Arabia’s, is shrinking, with the biggest collapse in investment in energy in 25 years. More than 140,000 have lost energy jobs. Banks are bracing for tens of billions of dollars of defaults, and economists and lawyers predict the financial wreckage will accelerate this year.”¹³⁶⁸
- March 10, 2016 – Crude oil production is not falling as quickly as predicted, given the sharp decline in prices and the drop-off in new drilling and fracking operations. As reported by Reuters, this disconnect is due to refracking of older wells, along with other unconventional techniques such as “choking” and “lifting,” which can extend the productive lives of wells or otherwise capture more product from them.¹³⁶⁹
- March 1, 2016 – An analysis of fracking trends in the journal *Nature* concluded that a European shale gas boom was unlikely due to disappointing early yields (Poland, Lithuania and Denmark), links to earthquakes (United Kingdom), and intense public opposition in densely populated areas throughout the continent.¹³⁷⁰
- June 19, 2015 – A *Bloomberg Business* analysis of the 62 drilling companies in the Bloomberg Intelligence North America Independent Exploration and Production Index found that the companies’ debt continued to be a major problem. For 27 of the 62 companies, interest payments were consuming more than 10 percent of revenue. Drillers’ debt rose to \$235 billion at the end of the first quarter, a 16 percent increase over the year

prior. *Bloomberg Business* expressed concern that shale drillers have “consistently spent money faster than they’ve made it, even when oil was \$100 a barrel.” S&P assigned speculative, or junk, ratings to 45 of the 62 companies in Bloomberg’s index.¹³⁷¹

- April 7, 2015 – A Moody’s Investors Service analysis of liquefied natural gas (LNG) prospects found that lower oil prices were causing suppliers to defer or cancel most proposed LNG projects. Moody’s found that this was due in part to the drop in international oil prices relative to U.S. natural gas prices, thus removing the economic advantage of U.S. LNG projects. Moody’s stated, “LNG is a capital-intensive infrastructure business prone to periodic construction cycles that lead to overcapacity, which we expect will continue for the rest of the decade.”¹³⁷²
- March 20, 2015 – A study by the Energy Watch Group in Germany found that the costs of allowing fracking in Germany would outweigh the benefits, noting in part that natural gas trading in the United States has been declining since 2009. The study also noted the costs of infrastructure, environmental and health risks and pointed to the need to expand renewable energy.¹³⁷³
- December 19, 2014 – An International Energy Agency (IEA) report projected that U.S. domestic oil supplies, dominated by fracking, face challenges, and oil output from shale formations output, will level off and decline in the early 2020s.¹³⁷⁴ IEA Chief Economist Fatih Birol said, “A well-supplied oil market in the short-term should not disguise the challenges that lie ahead.”¹³⁷⁵
- August 29, 2014 – Andrew Nikiforuk, a Canadian energy analyst, reported on diminishing returns and the higher-cost, higher-risk nature of fossil fuel extraction by fracking. Nikiforuk wrote, “Most of the world’s oil and gas firms are now pursuing extreme hydrocarbons because the cheap and easy stuff is gone.... That means industry will spend more good money chasing poor quality resources. They will inefficiently mine and frack ever larger land bases at higher environmental costs for lower energy returns.”¹³⁷⁶

- July 29, 2014 – According to the U.S. Energy Information Administration, energy companies are incurring increasing debt and selling assets to continue drilling in shale. “Based on data compiled from quarterly reports, for the year ending March 31, 2014, cash from operations for 127 major oil and natural gas companies totaled \$568 billion, and major uses of cash totaled \$677 billion, a difference of almost \$110 billion. This shortfall was filled through a \$106 billion net increase in debt and \$73 billion from sales of assets . . .”¹³⁷⁷
- July 2014 – Researchers at the Washington, DC-based Environmental Law Institute and Washington & Jefferson College in Pennsylvania collaborated to produce a report designed in part to help communities avoid the “boom and bust” cycles of extractive industries. Authors warned, “While resource extraction has long been regarded as an economic benefit, a body of academic literature suggests that long term growth based chiefly on resource extraction is rare.” Confounding factors include transience of the workforce, localized inflation, widening disparities in royalties and impact fee disbursement, commodity price volatility, and communities overspending on infrastructure.¹³⁷⁸
- June 19, 2014 – Energy analyst Deborah Lawrence Rogers outlined the spiraling debt and severe deterioration of the assets of five major shale gas drillers over the last five years. She concluded, “This is not sustainable. It could be argued that it is not even moral. It is a failed business model of epic proportion. While companies could make the argument at one time that this was a short term downtrend, that no longer holds water because this pattern is long term.”¹³⁷⁹
- April 10, 2014 – A report by a petroleum geologist and petroleum engineer concluded the 100-year supply of shale gas is a myth, distinguished between what is technically recoverable and economically recoverable shale gas, and asserted that at current prices, New York State has no economically recoverable shale gas.¹³⁸⁰
- February 28, 2014 – Maria van der Hoeven, Executive Director of the IEA, said in an interview with *The Christian Science Monitor* that there is only a decade left in the U.S. shale oil and gas boom, noting that her agency’s analysis predicts that production will soon flatten out and, by 2025, begin to decline.¹³⁸¹

- December 18, 2013 – A University of Texas study in *Proceedings of the National Academy of Sciences* found that fracking well production drops sharply with time, which undercuts the oil and gas industry’s economic projections.¹³⁸² In an interview about the study with *StateImpact NPR* in Texas, Tad Patzek, Chair of the Department of Petroleum and Geosystems Engineering at University of Texas at Austin, noted that fracking “also interferes now more and more with daily lives of people. Drilling is coming to your neighborhood, and most people abhor the thought of having somebody drilling a well in their neighborhood.”¹³⁸³
- August 18, 2013 – *Bloomberg News* reported that low gas prices and disappointing wells have led major companies to devalue oil and gas shale assets by billions of dollars.¹³⁸⁴
- October 21, 2012 – The *New York Times* reported that many gas drilling companies overproduced natural gas backed by creative financing and now “are committed to spending far more to produce gas than they can earn selling it.” “We are all losing our shirts today,” said Exxon CEO Rex Tillerson in the summer of 2012.¹³⁸⁵
- July 13, 2012 – *The Wall Street Journal* reported that ITG Investment Research, at the request of institutional investors, evaluated the reserves of Chesapeake Energy Corporation’s shale gas reserves in the Barnett and Haynesville formations and found them to be only 70 percent of estimates by Chesapeake’s engineering consultant for the company’s 2011 annual report. Chesapeake and its consultant defended their figures.¹³⁸⁶
- August 23, 2011 – The U.S. Geological Survey (USGS) cut the government’s estimates of natural gas in the Marcellus Shale from 410 trillion cubic feet to 84 trillion cubic feet, equivalent to a reduction from approximately 16 years of U.S. consumption at current levels of natural gas use, to approximately 3.3 years of consumption. The USGS’s updated estimate was for natural gas that is technically recoverable, irrespective of economic considerations such as the price of natural gas or the cost of extracting it.¹³⁸⁷

Disclosure of serious risks to investors

A snapshot of the dangers posed by natural gas drilling and fracking can be found in the annual Forms 10-K that oil and natural gas companies are required to file with the U.S. Securities and Exchange Commission (SEC). The information so contained in these reports, which provide a comprehensive summary of a company's financial performance, provides a window into the harms and risks of fracking that are otherwise shielded from view by "gag order" clauses in court settlements, non-disclosure agreements between industry and landowners, and trade secret claims in regards to the chemical ingredients of fracking fluid. In this way, the Form 10-K can serve as an imperfect surrogate for right-to-know data. Recently, Forms 10-K have been used to warn investors about risks from climate change lawsuits.

Federal law requires that companies offering stock to the public disclose in their Form 10-K, among other things, the "most significant factors that make the offering speculative or risky."¹³⁹⁴ In a review of Forms 10-K spanning the past decade available on the SEC's website, oil and natural gas companies have routinely warned of drilling's serious risks. In the words of Exxon Mobil Corporation's subsidiary XTO Energy, "our operations are subject to hazards and risks inherent in drilling."¹³⁹⁵ In the language of Range Resources Corporation: "development and exploratory drilling and production activities are subject to many risks."¹³⁹⁶

Such hazards and risks include leaks, spills, explosions, blowouts, environmental damage, property damage, injury, and death. Chesapeake Energy Corporation has stated that "horizontal and deep drilling activities involve greater risk of mechanical problems than vertical and shallow drilling operations."¹³⁹⁷ Over the past 15 years, companies have combined horizontal drilling with hydraulic fracturing to tap natural gas and oil in shale formations.

The companies also routinely warn of inadequate insurance to cover drilling harms. According to XTO Energy, "we are not fully insured against all environmental risks, and no coverage is maintained with respect to any penalty or fine required to be paid by us."¹³⁹⁸ Range Resources states, "we can provide no assurance that our coverage will

¹³⁹⁴ See 17 C.F.R. § 229.503(c) (companies must disclose the "most significant" risks); 17 C.F.R. § 230.405 ("the term material, when used to qualify a requirement for the furnishing of information as to any subject, limits the information required to those matters to which there is a substantial likelihood that a reasonable investor would attach importance in determining whether to purchase the security registered"); 17 C.F.R. § 240.10b-5 (it is illegal "to make any untrue statement of a material fact or to omit to state a material fact . . . in connection with the purchase or sale of any security"); 17 C.F.R. 249.310 (requiring Form 10-K, "for annual and transition reports pursuant to sections 13 or 15(d) of the Securities Exchange Act of 1934.")

¹³⁹⁵ XTO Energy Corp., Annual Report (Form 10-K) (Feb. 25, 2010) at 25.

¹³⁹⁶ Range Resources Corp., Annual Report (Form 10-K) (Feb. 24, 2015) at 22.

¹³⁹⁷ Chesapeake Energy Corp., Annual Report (Form 10-K) (Feb. 27, 2015) at 18.

¹³⁹⁸ XTO Energy Corp., Annual Report (Form 10-K) (Feb. 25, 2010) at 17.

adequately protect us against liability from all potential consequences, damages and losses.”¹³⁹⁹

Houston-based Noble Energy provides a representative example of the risks that at least several drilling companies include in their annual reports. Noble states:

Our operations are subject to hazards and risks inherent in the drilling, production and transportation of crude oil, natural gas and NGLs [natural gas liquids], including:

- injuries and/or deaths of employees, supplier personnel, or other individuals;
- pipeline ruptures and spills;
- fires, explosions, blowouts and well cratering;
- equipment malfunctions and/or mechanical failure on high-volume, high-impact wells;
- leaks or spills occurring during the transfer of hydrocarbons from an FPSO [floating production storage and offloading vessels] to an oil tanker;
- loss of product occurring as a result of transfer to a rail car or train derailments;
- formations with abnormal pressures and basin subsidence which could result in leakage or loss of access to hydrocarbons;
- release of pollutants;
- surface spillage of, or contamination of groundwater by, fluids used in operations;
- security breaches, cyber attacks, piracy, or terroristic acts;
- theft or vandalism of oilfield equipment and supplies, especially in areas of active onshore operations;
- hurricanes, cyclones, windstorms, or “superstorms,” which could affect our operations in areas such as the Gulf Coast, deepwater Gulf of Mexico, Marcellus Shale or Eastern Mediterranean;
- winter storms and snow which could affect our operations in the DJ Basin [Denver-Julesburg Basin in Colorado] or Marcellus Shale;
- extremely high temperatures, which could affect third party gathering and processing facilities in the DJ Basin;
- volcanoes which could affect our operations offshore Equatorial Guinea;
- flooding which could affect our operations in low-lying areas;
- harsh weather and rough seas offshore the Falkland Islands, which could limit certain exploration activities; and
- pandemics and epidemics, such as the Ebola virus, which is ongoing in certain regions of West Africa and may adversely affect our business operations through travel or other restrictions.

Any of these can result in loss of hydrocarbons, environmental pollution and other damage to our properties or the properties of others.¹⁴⁰⁰

Noble has language similar to that found in other companies’ annual reports about inadequate insurance and adds, “we do not have insurance for gradual pollution nor do

¹³⁹⁹ Range Resources Corp., Annual Report (Form 10-K) (Feb. 24, 2015) at 26.

¹⁴⁰⁰ Noble Energy, Annual Report (Form 10-K) (Feb. 19, 2015) at 38.

we have coverage for penalties or fines that may be assessed by a governmental authority.”¹⁴⁰¹

Forms 10-K are also a tool of disclosure for risks concerning climate change beyond specific negative impacts on operations (hurricanes, flooding, etc.) listed, for example, in Noble Energy’s annual report cited above. In 2016, Chevron became the first major oil company to warn investors in its Form 10-K about the risk of climate change lawsuits: “Increasing attention to climate change risks has resulted in an increased possibility of governmental investigations and, potentially, private litigation against the company.”¹⁴⁰² Also in 2016, the SEC began investigating Exxon Mobil for valuing its assets in ways that do not account for the possible depreciation of oil and gas under a policy framework that shifts investments in energy away from fossil fuels and toward renewable sources.¹⁴⁰³ Under pressure from investors, Exxon agreed in December 2017 to disclose more details about climate risks by filing with the SEC, in a Form 8-K, a statement that said the company would no longer resist motions from shareholders seeking this information.¹⁴⁰⁴

At this writing, it is not clear whether, under the current Administration, the SEC will continue its push toward investor disclosure of climate change risks.¹⁴⁰⁵ Nevertheless, the unsolved problem of methane leaks is increasingly recognized as a rising risk for oil and gas investors concerned that methane emissions are not transparently managed, may negate the claim that natural gas is more climate-friendly than coal, and hence pose a risk to their investments.^{1406, 1407}

The risks identified by these oil and gas companies are not just hypothetical. Many, if not all of these risks are reflected in the evidence compiled in other sections of this Compendium.

Medical and scientific calls for more study, reviews confirming evidence for harm, and calls for increased transparency and science-based policy

With increasing urgency, groups of medical and other health professionals and scientists are issuing calls for comprehensive, long-term study of the full range of potential health and ecosystem effects of drilling and fracking. These appeals underscore the accumulating evidence of harm, point to the major knowledge gaps that remain, and decry the atmosphere of secrecy and intimidation that continues to impede the progress of scientific inquiry. Published reviews and international governmental reports underscore the mounting evidence of health risks including developmental, neurological, carcinogenic, respiratory, reproductive, and psychological. Health professionals and scientists in the United States and around the world increasingly call for the suspension of unconventional gas and oil extraction activities in order to limit, mitigate, or eliminate its serious, adverse public health hazards, including health threats from climate change.

- March 29, 2019 – Doctors for the Environment Australia announced the reinforcement of its position that no new gas extraction of any kind should occur in Australia. Its position was largely informed by the wealth of literature from the United States documenting adverse health findings.¹⁴⁰⁸ The organization’s review found growing evidence of direct health impacts as well as a clear potential for indirect impacts of gas and oil mining on essential environmental determinants of health. “These concerns include risks to a stable climate, air quality, water quality, water security, food security, community cohesion and, in some locations, geological stability. The cumulative impacts of these industries on the wider requirements for good health and wellbeing are extremely concerning.”¹⁴⁰⁹
- February 1, 2019 – Natural gas extraction via fracking is associated with “preterm birth, high-risk pregnancy, and possibly low birth weight; three types of asthma exacerbations; and nasal and sinus, migraine headache, fatigue, dermatologic, and other symptoms,” according to a review covering research through mid-2017.¹⁴¹⁰ The Johns Hopkins Bloomberg School of Public Health scientists cited the methodological robustness of these studies and the biological plausibility of the links found. Further, they included in their review the contribution of fracking to climate change and its further health impacts. Authors expressed serious doubt that the risks of fracking can be managed. “Some have suggested that regulations will prevent health impacts, but no health studies provide guidance on what regulations, if any, will get the health effects to go away.” The authors further noted that the fracking boom has, in many regions, outpaced the ability of science

to document health impacts with long latencies, such as cancer and neurodegenerative diseases. The review concluded that the results of early health studies “should give pause” about whether and how shale gas fracking should proceed and referenced the several U.S. states and nations that have disallowed fracking, citing health concerns.

- December 12, 2018 – “The healthcare community has a professional mandate to protect society from harm to human health. We have a responsibility to help society move away from fossil fuels and accelerate the transition to renewable energy,” wrote a team of medical professionals in an editorial for the *British Medical Journal*. Citing the “overwhelming” evidence that fossil fuels pose serious threats to public and planetary health, the group identified divestment from fossil fuel corporations as a strategy that increasing numbers of medical professional groups are taking, as part of fulfilling that professional mandate.¹⁴¹¹
- December 4, 2018 – In a review of 63 studies in 20 countries, a University of Southern California medical research team concluded that the potential public health effects of “upstream oil extraction” include cancer, liver damage, immunodeficiency, and neurological damage. Collectively, onshore operations that bring crude oil to the surface affect nearly six million people that live or work nearby. Community health, worker health, and animal health in oil-drilling regions were addressed in this review, as well as effects on soil, air, surface water, and drinking water quality. In their analysis, the authors included both conventional or unconventional extraction techniques but noted that, in the United States, hydraulic fracturing accounted for 50 percent of total oil production in 2015—up from less than two percent in 2000.¹⁴¹²
- August 16, 2018 – The closer one lives to fracking sites, the more likely one is to experience toxic exposures and a related number of health impacts. Setbacks less than one quarter mile (1,320 feet) from drilling and fracking operations are not sufficient to protect public health, and additional setbacks are needed to protect vulnerable groups and settings, according to an expert panel assembled in Pennsylvania. “Vulnerable groups were defined by the panelists as children, neonates, fetuses, embryos, pregnant women, elderly individuals, those with pre-existing medical or psychological conditions, and those with pre-existing respiratory conditions. Vulnerable settings were defined as schools, day care centers, hospitals, and long-term care facilities. The panel, which consisted of 18 health care providers, public health practitioners, environmental advocates, and researchers/scientists, was brought together to compare existing minimum setback requirements against research about the health impacts of living near fracking activity. The panel was unable to come to agreement on a minimum safe setback distance between one quarter and two miles. It also noted that the failure to achieve consensus on this issue reflects uncertainties based on limited data of real-time toxic emissions from

drilling and fracking operations, the limited number of scientific studies available, and the potential for episodically recurrent periods of high exposures.¹⁴¹³

- June 5, 2018 – The exacerbation of climate change caused by shale gas development is sufficient grounds to confirm that “the risks clearly and considerably outweigh any possible benefits,” according to two public health scholars who published their editorial in the *British Medical Journal*.¹⁴¹⁴
- May 9, 2018 – With the objective of making practical recommendations for primary care providers, researchers sought to identify all published peer-reviewed studies examining evidence of direct relationships between high-volume hydraulic fracturing and human health harms. As a scoping review, the study purpose was to examine the extent and breadth of research and identify research gaps. Their criteria for inclusion were “narrow” and included peer-reviewed journal articles from the United States, in English, published between 2000 and September 2017. Among the 18 studies selected, 10 showed a positive correlation to the negative health outcome, six showed a mixed relationship, and two found no relationship. The authors wrote, “The health impacts found in the limited studies in this scoping review should encourage health care providers to maintain a high index of suspicion with patients who live or have lived near [drilling and fracking] activity or who have worked in oil and gas fields.”¹⁴¹⁵
- April 4, 2018 – Two scholars critiqued the wide-ranging consultation on unconventional gas extraction, including fracking, which was commissioned by the Scottish government and published in November 2016.¹⁴¹⁶ Noting that the Scottish assessment is more comprehensive than assessments conducted in the United States and elsewhere, the authors wrote, “The public health impact assessment in particular is underpinned by what appears to be a rigorous and transparent examination of existing scientific literature drawing on external peer review at some stages.” However, they also went on to say that some of the conclusions drawn “appear to be optimistic readings of data and experience. For example, assessments of the ability of industry and regulators to control fracking effects on public health do not stand up to scrutiny.” They identified several other ways in which the health impact assessment’s conclusions were not always supported by the evidence it reviewed and if the assessment had overlooked areas of concern. For example, the literature on social impact assessments, as well as health research addressing questions of well-being and mental health, were neglected. Nevertheless, these scholars recommended the Scottish consultation as a research and policy tool.

- February 12, 2018 – The Los Angeles County Department of Public Health reviewed the public health and safety risks of oil and gas facilities and identified “next steps.” These included an increase in setback distances, continuous air monitoring systems around oil and gas operations, increased local oversight, a comprehensive Community Safety Plan, and Emergency Preparedness Plans. For this report, authors reviewed epidemiological literature, environmental and health impact assessments, neighborhood health investigations, and consultations with various jurisdictions regarding oil and gas ordinances.¹⁴¹⁷ At the time of the report preparation, there were 3,468 active and 1,850 inactive oil and gas wells countywide. Conditions varied widely. Among the most egregious was an active well that was located 60 feet from a multi-unit housing complex and that shared borders with a local high school and a college dormitory. “The potential public health impacts of oil and gas sites located in densely populated areas are concerning, particularly to those who experience disproportionate economic and health inequities.” Recommendations for some individual neighborhoods included offering temporary relocation assistance. “The report was ordered by the city of Los Angeles after complaints of headaches, eye and throat irritation, nausea and vomiting were received from residents of South Los Angeles, Wilmington and unincorporated county areas in the past several years.”¹⁴¹⁸
- December 12, 2017 – Commissioned by the Australian government, the Scientific Inquiry into Hydraulic Fracturing in the Northern Territory released its Draft Final Report. Tasked with identifying and assessing the risks of shale gas fracking for Australia’s remote Northern Territory—and with making recommendations to mitigate those risks where possible—the Inquiry describes a multiplicity of risks, including many that are ill-defined and understudied¹⁴¹⁹ Most notably, it recommends a halt on all fracking production licenses until a two-to-three-year study can be launched to further understand the nature of the risks for the particular ecology and culture of the region.”¹⁴²⁰ Fracking is currently prohibited in the Northern Territory, which is estimated to hold over one-third of Australia’s shale gas.
- November 7, 2017 – In a commentary published in *JAMA*, two South Dakota physicians reviewed the data on the potential public health implications of fracking, including asthma, water contamination, exposures to fracking fluid, and exposure of workers to

silica dust. They voiced specific concerns about parkinsonism, neuropathy, and kidney disease, and called for prospective toxicity studies.¹⁴²¹

- October 25, 2017 – Scientists and physicians (including two co-authors of this *Compendium*) reviewed the body of evidence on the potential of unconventional oil and natural gas (UOG) development and operations to contribute to neurological and developmental harm via increased air and water pollution in the surrounding communities where it takes place. Highlighting data gaps and research limitations (such as the nondisclosure by industry of chemical mixtures), they nevertheless pinpointed evidence in the existing literature showing that “the chemicals that are used in or are byproducts of UOG operations have been linked to serious neurodevelopmental health problems in infants.”¹⁴²² Interviewed by the *Guardian*, a co-author said, “Given the profound sensitivity of the developing brain and the central nervous system, it is very reasonable to conclude that young children who experience frequent exposure to these pollutants are at particularly high risk for chronic neurological problems and disease.”¹⁴²³ The research team concluded that there is “a need for public health prevention techniques, well-designed studies, and stronger state and national regulatory standards.”
- October 23, 2017 – A Yale University research team reported that carcinogens involved in fracking operations have the potential to contaminate both air and water in nearby communities in ways that may increase the risk of childhood leukemia. The team identified 55 known or possible carcinogens that may be released into air and water from fracking operations. Of these, 20 are linked to leukemia or lymphoma.¹⁴²⁴ “This analysis creates a priority list of carcinogens to target for future exposure and health studies.”¹⁴²⁵
- July 31, 2017 – A review by a team of medical, psychological, occupational, and environmental health professionals concluded, “there appears to be an array of levels of psychosocial functioning that are deleteriously affected by the fracking process and industries and their aftermath.” Though much of the research they identified linking fracking to psychological functioning was preliminary, documented impacts included: individual-level impacts, such as feelings of stress and powerlessness; community-level impacts, such as disrupted social fabric and new gender/sex imbalances in the community; collective trauma such as caused by a boom-and-bust cycle; and worker impacts, such as psychosocial impacts of being a transient worker. The review provided

“an important first step in understanding the psychological toll that this energy development strategy has on fracking communities and sets the stage for advancements in research, clinical and policy, that will help us to better understand, assist, and advocate for those affected by fracking.”¹⁴²⁶

- May 1, 2017 – The Southwest Pennsylvania Environmental Health Project established a voluntary public health registry “aimed at tracking and eventually analyzing the impacts of shale gas development on people living near wells, impoundments, compressor stations and pipelines.” According to a spokesperson, “The point is that the vast majority of independent science is looking at [shale gas development] and saying something’s not good there. We need to know more... The findings of this registry will allow the health care community to be more informed about what problems people are experiencing when they walk into their offices. It will give the doctors some idea of what they should be looking for.”¹⁴²⁷
- April 28, 2017 – Portuguese and Brazilian reviewers identified the issue of water resources “as one of the most sensitive to negative impacts by shale gas exploration and exploitation,” in their examination of scientific articles published between 2010 and 2015. They pointed to “expected” new legislation and industry practices for impact reductions but continued on to say that there are “no indications of a solution in the near future” for the problems of wastewater and greenhouse gas emissions.¹⁴²⁸
- February 8, 2017 – Addressing the community health and safety harms linked with camps that house temporary workers in extractive industries, the British Columbia Ministry of Aboriginal Relations and Reconciliation funded a research project carried out in consultation with Indigenous nations. The premise, that “Indigenous women and youth can experience negative impacts of resource extraction at every phase of resource development,” was borne out by the project’s community dialogues and literature review. “Increased domestic violence, sexual assault, substance abuse, and an increased incidence of sexually transmitted infections (STIs) and HIV/AIDS due to rape, prostitution, and sex trafficking are some of the recorded negative impacts of resource extraction projects, specifically as a result of the presence of industrial camps and transient work forces.” The objectives of the project were to stimulate dialogue and to develop detailed protective steps for Nations, government, and industry in advance of the initiation of planned extraction projects in the region, such as the TransCanada and Spectra Energy pipelines,

in order to prevent violence against women and other life changing negative effects linked to the industrial camps.¹⁴²⁹

- February 8, 2017 – Los Angeles County health officials criticized as insufficient the allocation of only one million dollars by the Southern California Gas Company to fund an independent health study in the aftermath of the massive methane leak at Aliso Canyon that lasted from October 2015 until February 2016. “‘It’s a study, but not a health study,’ said Angelo Bellomo, the Los Angeles County deputy director for health protection. ‘It is not responsive to addressing the health needs and concerns to this community. More importantly, it’s inconsistent with advice given to [South Coast Air Quality Management District] by health officials.’” Health experts from across the state had suggested a design “that was comprehensive and larger in scope as well as consistent with a state Senate bill introduced last year that estimated such a design would cost \$13 million in the first three years, and up to \$40 million to complete.”¹⁴³⁰
- January 19, 2017 – An epidemiologist at Brown University reviewed studies to date on health outcomes in communities living close to unconventional natural gas development, and identified areas requiring further study. “Future epidemiologic studies should implement personal exposure assessments to examine associations between individual contaminants and relevant health outcomes, particularly to explain associations seen with respiratory and birth outcomes,” the author concluded.¹⁴³¹
- December 5, 2016 – A team of British scientists wrote a 156-paper review on the risks and harms of fracking that attempts to “capture, review and interpret the published literature across all the accepted domains of public health in a systematic way and consider specific implications for the UK.” They concluded that shale gas fracking “unequivocally presents an exposure hazard,” and that further studies were needed to address exposure and health outcome data, noting the lack of before, during, and after exposure data for both air and water around drilling and fracking sites. Authors also noted that the claims that shale gas is less harmful to the climate than coal are not backed by lifecycle analyses. This team called for more research and a delay on any proposed drilling and fracking activity in the United Kingdom.¹⁴³²

- November 1, 2016 – The government of Scotland released a health impact assessment that reconfirmed the evidence for potential contamination of air and water, threats to worker health from silica dust exposure, and risks to the health of nearby residents.¹⁴³³
- October 23, 2016 – In a unanimous vote of the society’s 300-member House of Delegates, the Pennsylvania Medical Society called for a moratorium on new shale gas drilling and fracking in Pennsylvania and an initiation of a health registry in communities with pre-existing operations.^{1434, 1435}
- October 11, 2016 – A group of health care professionals in Massachusetts called for an immediate moratorium on major new natural gas infrastructure until the impact of these projects on the health of the communities affected can be adequately determined through a Comprehensive Health Impact Assessment.¹⁴³⁶ The group noted that the operation of natural gas facilities risks human exposures to toxic, cancer-causing, and radioactive pollution due to the presence of naturally co-occurring contaminants, toxic additives to the hydraulic fracturing process, and through the operation of transmission pipelines.¹⁴³⁷
- September 15, 2016 – A systematic review of 45 studies, primarily but not exclusively addressing conventional oil and gas activities, showed an emerging body of evidence documenting harm to reproductive health from residential and occupational exposure to these operations. The strongest evidence existed for increased risk of miscarriage, prostate cancer, birth defects, and decreased semen quality. Authors state that there is “ample evidence for disruption of the estrogen, androgen, and progesterone receptors with individual chemicals and waste products related to oil and gas extraction,” and “impacts from unconventional oil and gas activities will likely be greater, given that unconventional activities have many similarities to conventional ones and employ dozens of endocrine-disrupting chemicals in the process of hydraulic fracturing.”¹⁴³⁸
- September 14, 2016 – In a commentary about fracking in the *American Journal of Public Health*, Weill Cornell Medicine physicians wrote, “mounting empirical evidence shows harm to the environment and to human health . . . and we have no idea what the long-

term effects might be. . . . Ignoring the body of evidence, to us, is not a viable option anymore.”¹⁴³⁹

- July 7, 2016 –The UK health professional organization Medact released an updated assessment of the potential health impacts of shale fracking in England that confirm the findings of its 2015 report, *Health and Fracking*. The new report, *Shale Gas Production in England*, concluded, “Our view that the UK should abandon its policy to encourage [shale gas production] remains unchanged.” The new report included hundreds of new academic papers addressing impacts on air and water quality, health, climate change, social wellbeing, economics, noise and light pollution, and seismic events. Still, authors wrote, “the absence of an independent social, health and economic impact assessment of [shale gas production] at scale is a glaring omission. Given the availability of alternative sources of energy, these are grounds for placing an indefinite moratorium on SGP (a position adopted by many jurisdictions across the world) until such time that there is greater clarity and certainty about the relative harms and benefits of shale gas.”¹⁴⁴⁰
- May 31, 2016 – “There are too many science, technology and risk-assessment gaps to green-light fracking in western Newfoundland,” according to a panel that studied the question. In an interview with Canada’s *Globe and Mail*, panel leader and engineering professor Ray Gosine said, “The science, the studies that have been done, have been somewhat limited – certainly limited compared to what we’d expect to have done in order to plan this kind of operation. . . . There are a number of gaps and deficiencies that are significant.”¹⁴⁴¹
- May 13, 2016 – Physicians for Social Responsibility called for a ban on hydraulic fracturing, pointing both to the irremediable climate harm caused by methane emissions as well to the multiple health risks from industrial-scale water consumption, air pollution, seismic effects, the generation of large quantities of toxic liquid waste, and long-term impacts on drinking water aquifers. “We cannot stay healthy in an unhealthy environment. Nor can we survive indefinitely on a planet growing hotter and more prone to extreme, unpredictable and destructive weather. These factors impel PSR to call for a ban on fracking and for a rapid transition to cleaner, healthier, carbon-free sources of energy.”¹⁴⁴²
- March 27, 2016 – Noting that many chemicals used in fracking fluids are known or suspected endocrine disruptors, a group of public health researchers called for an endocrine-centric component for health assessments in areas impacted by oil and gas operations. The team outlined a series of recommendations to assess the “potential

endocrine-related risks from chemical exposures associated with oil and natural gas operations. We present these recommendations in light of the growing body of information regarding both chemical concentrations in the environment and adverse health outcomes reported in humans and wildlife.”¹⁴⁴³

- January 6, 2016 – A Yale University team of epidemiologists called for a systematic evaluation of chemicals in fracking fluid and wastewater for reproductive and development toxicity. While basic toxicity information is lacking for more than three-quarters of the more than 1,000 chemicals known to be used in fracking fluid, many of the remainder, the authors note, are linked to reproductive and developmental harm. “Therefore, carefully designed, rigorous exposure, and epidemiologic studies are urgently needed to investigate public health uncertainties... The 67 chemicals we identified as possibly associated with either reproductive or developmental toxicity with a current or proposed federal drinking water standard or health-based guideline represent a feasible starting point for evaluation in future drinking water exposure studies or human health studies....”¹⁴⁴⁴
- November 24, 2015 – A Harvard University team identified a trend toward increasing chemical secrecy and less transparency by examining 96,000 chemical disclosure forms filed by fracking companies between March 2011 and April 2015. These forms were submitted to the Fracfocus website, a chemical disclosure portal for the fracking industry that operates on a voluntary basis but for which reporting is mandated in more than 20 states. Fracfocus is the largest public database on chemicals used in U.S. fracking operations.¹⁴⁴⁵ Companies involved in fracking withheld chemical data at significantly higher rates in 2015 (16.5 percent) as compared to 2011-2013 (11 percent). The research team also found that withholding drops by a factor of four when companies report aggregate data without attribution to the specific products in the fracking fluid. The authors called for state governments to retain authority in requiring disclosure of “product-specific ingredient lists.”¹⁴⁴⁶
- August 7, 2015 – While acknowledging the “dramatic increase in the number of peer-reviewed published studies” on environmental and health impacts of fracking, Weill Cornell Medical College’s Dr. Madelon Finkel and co-author PSE Healthy Energy’s Jake Hays called for more well-designed longer-term epidemiologic studies to quantify the connections between fracking-related risk factors and health outcomes. Without such studies it is challenging to capture, for example, outcomes such as cancer that take many

years to present. The authors described several important studies that are currently underway that will add to the body of knowledge in the future.¹⁴⁴⁷

- June 9, 2015 – Information on individual exposures and local environmental conditions prior to the commencement of fracking in a given area is often “unavailable or hard to obtain. These and other data gaps have hindered the kind of large-scale epidemiological studies that can link exposures to actual health outcomes, with valid comparison groups,” wrote public health journalist David Tuller in the journal *Health Affairs*.¹⁴⁴⁸ In an interview with *Michigan Radio*, Tuller noted that, because well development happens quickly, there was generally a lack of pre-drilling baseline studies.¹⁴⁴⁹
- April 17, 2015 – Using sophisticated Geographic Information Systems (GIS) tools to examine distribution of fracking wells compared to distribution of vulnerable populations, Clark University researchers found consistent evidence that, in the Pennsylvania Marcellus Shale region, census tracts with potential exposure to pollution from fracking wells contained “significantly higher” percentages of poor people. They also found clusters of vulnerable populations concentrated near drilling and fracking in all three states they studied: Pennsylvania (for poverty and elderly population), West Virginia (for poverty, elderly population, and education level) and Ohio (for children). Researchers also reported difficulty in accessing high quality and consistent unconventional well data in all three states, demonstrating an “urgent need” for common data collection and reporting.¹⁴⁵⁰ Another GIS-based study sought to begin to fill this gap in data on spatially distributed risks of fracking, identifying Pennsylvania populations at “very high” and “high” risk in over a dozen counties. The author called for more focus on those areas to understand the impacts of fracking.¹⁴⁵¹
- March 30, 2015 – The UK medical organization Medact published a report, *Health & Fracking: The Impacts and Opportunity Costs*, which concluded that fracking poses significant risks to public health and called for an immediate moratorium to allow time for a full and comprehensive health and environmental impact assessment to be completed.¹⁴⁵² The report was supported by a letter published in the *British Medical Journal* calling for shale gas development to be put on hold, signed by the Climate and Health Council and over a dozen senior health professionals. The letter stated, “The arguments against fracking on public health and ecological grounds are overwhelming.

There are clear grounds for adopting the precautionary principle and prohibiting fracking.”¹⁴⁵³

- February 17, 2015 – Writing in the *Canadian Medical Association Journal*, a public health scientist and medical doctor briefly reviewed the human health risks of fracking documented to date and made the case for a health care worker role in insisting on improved understanding. They cited worker and community safety issues as the biggest short-term risks, but emphasized that more needs to be known “before health care providers can definitively respond to their patients’ and communities’ concerns.... Physicians may wish to advocate delaying new development activities until the potential health effects are better understood.”¹⁴⁵⁴
- January 22, 2015 –The acting head of research at the Cancer Association of South Africa, Carl Albrecht, said that known carcinogenic chemicals used in fracking could lead to an epidemic of cancer in South Africa’s Karoo desert. As South Africa was poised to publish draft regulations, Albrecht said that the effect of fracking on human health was ignored.¹⁴⁵⁵
- January 19, 2015 – In an article that reviewed research and research gaps, a team of British and U.S. medical and scientific professionals urged the United Kingdom and other nations to engage in science before engaging in fracking. They warned that even strong regulations may not effectively address air pollution from fracking, and that “permanent, adverse environmental, climatic, and population health impacts” may exist in some cases.¹⁴⁵⁶
- December 17, 2014 – In an editorial, Rutgers University environmental exposure expert Paul J. Liroy (now deceased) highlighted fracking as an area in which accurate exposure monitoring and risk assessment did not yet exist. Liroy emphasized that the relevant research was compartmentalized and fragmented and that exposures and health outcomes around unconventional natural gas development need to be systematically addressed through “well-defined exposure studies in communities and workplaces.”¹⁴⁵⁷

¹⁴⁵⁷ Liroy, P.J. (2015). Exposure science and its places in environmental health sciences and risk assessment: Why is its application still an ongoing struggle in 2014? *Journal of Exposure Science and Environmental Epidemiology*, 25, 1-3. doi: 10.1038/jes.2014.59

Albany, reviewed the scientific evidence that both adult and early life—including prenatal—exposure to chemicals from fracking operations can result in adverse reproductive health and developmental effects. These include: endocrine-disrupting chemicals potentially increasing risk for reproductive problems, breast cancer, abnormal growth and developmental delays, and changes in immune function; benzene, toluene and xylene (BTX chemicals) increasing risk for impaired sperm quantity and quality in men and menstrual and fertility problems in women; and heavy metals increasing the risk of miscarriage and/or stillbirths. Potential exposures occur through both air and water. Based on their review, the authors concluded, “Taken together, there is an urgent need for the following: 1) biomonitoring of human, domestic and wild animals for these chemicals; and 2) systematic and comprehensive epidemiological studies to examine the potential for human harm.”¹⁴⁵⁸ Lead author Susan Nagel said in an accompanying interview, “We desperately need biomonitoring data from these people. What are people actually exposed to? What are the blood levels of people living in these areas? What are the levels in the workers?”¹⁴⁵⁹

- November 12, 2014 – A team of Australian researchers reviewed the strength of evidence for environmental health impacts of fracking based on publications from 1995 to 2014. They noted that the rapid expansion of fracking had outstripped the pace of science and that most studies focused on short-term, rather than long-term, health. Hence, “very few studies examined health outcomes with longer latencies such as cancer or developmental outcomes.” Noting that no evidence exists to rule out health impacts, the team called for direct and clear public health assessments before projects are approved, longitudinal studies that include baseline data, and government and industry transparency.¹⁴⁶⁰
- September 15, 2014 – Researchers led by University of Rochester’s Environmental Health Sciences Center conducted interviews in New York, North Carolina, and Ohio to evaluate community health concerns about unconventional natural gas development. They identified many areas where more study is needed, including baseline measures of air quality, ongoing environmental monitoring, and health impact assessments. They noted that other areas where data are lacking involve the assessment of drilling and fracking impacts on vulnerable populations such as very young children, and the potential consequences of interactions between exposures resulting from shale gas extraction operations. Researchers suggested incorporating the input of potentially affected community members into the development of the research agenda.¹⁴⁶¹

- July 21, 2014 – An independent assessment report by Scientists for Global Responsibility and the Chartered Institute of Environmental Health reviewed current evidence across a number of issues associated with shale gas extraction by hydraulic fracturing, including environmental and public health risks, drawing on academic research. Among the report’s conclusions: there are major shortcomings in regulatory oversight regarding local environmental and public health risks; there is a large potential for UK shale gas exploitation to undermine national and international efforts to tackle climate change; the water-intensive nature of the fracking process which could cause water shortages in many areas; the complete lack of evidence behind claims that shale gas exploitation will bring down UK energy bills; and concerns that it will impact negatively on UK energy security. Despite claims to the contrary, the report noted that evidence of local environmental contamination from shale gas exploitation is well reported in the scientific literature. It emphasizes that, “[t]here are widespread concerns over the lack of evidence on fracking-related health impacts,” and that there is a lack of “substantive epidemiological study for populations exposed to shale gas extraction.”¹⁴⁶²
- July 18, 2014 – A working group of the Environmental Health Sciences Core Centers, supported by the National Institute of Environmental Health Sciences, reviewed the available literature on the potential health impacts of fracking for natural gas. They concluded that further research is urgently needed. Needs identified included: monitoring of air and water quality over the entire lifetime of wells; further epidemiologic research addressing health outcomes and water quality; and research addressing whether air pollution associated with fracking increases the risk of pulmonary and cardiovascular disease. The working group advocated for the participation of potentially affected communities in all areas of research.¹⁴⁶³
- July 12, 2014 – Eli Avila, Pennsylvania’s former Secretary of Health, said that health officials need to be proactive in protecting the public from the health effects of unconventional shale gas extraction. In 2011, funding was approved for a Pennsylvania public health registry to track drilling related complaints and address concerns, but was cut at the last minute. Speaking to the problem posed by the dearth of information, Avila asked, “How can you keep the public safe if you’re not collecting data?”¹⁴⁶⁴
- June 30, 2014 – The immediate past chair of the Executive Committee of the Council on Environmental Health for the American Academy of Pediatrics, Jerome A. Paulson, MD,

called for industry disclosure of all ingredients of fracking fluid; thorough study of all air contaminants released from drilling and fracking operations and their protected dispersal patterns; and study and disclosure of fracking-related water contamination and its mechanisms. In a letter to the Pennsylvania Department of Environmental Protection (PA DEP), Paulson said:

In summary, neither the industry, nor government agencies, nor other researchers have ever documented that [unconventional gas extraction] can be performed in a manner that minimizes risks to human health. There is now some evidence that these risks that many have been concerned about for a number of years are real risks. There is also much data to indicate that there are a number of toxic chemicals used or derived from the process, known or plausible routes of exposure of those chemicals to humans; and therefore, reason to place extreme limits on [unconventional gas extraction].¹⁴⁶⁵

- June 20, 2014 – Highlighting preliminary studies in the United States that suggest an increased risk of adverse health problems among individuals living within ten miles of shale gas operations, a commentary in the British medical journal *The Lancet* called for a precautionary approach to gas drilling in the United Kingdom. According to the commentary, “It may be irresponsible to consider any further fracking in the UK (exploratory or otherwise) until these prospective studies have been completed and the health impacts of fracking have been determined.”¹⁴⁶⁶
- June 20, 2014 – Led by an occupational and environmental medicine physician, a Pennsylvania-based medical and environmental science research team documented “... the substantial concern about adverse health effects of [unconventional natural gas development] among Pennsylvania Marcellus Shale residents, and that these concerns may not be adequately represented in medical records.” The teams identified the continued need to pursue environmental, clinical, and epidemiological studies to better understand associations between fracking, medical outcomes, and residents’ ongoing concerns.¹⁴⁶⁷
- June 17, 2014 – A discussion paper by the Nova Scotia Deputy Chief Medical Officer and a panel of experts identified potential economic benefits as well as public health concerns from unconventional oil and gas development. On the health impacts, they wrote, “uncertainties around long term environmental effects, particularly those related to climate change and its impact on the health of both current and future generations, are considerable and should inform government decision making.” The report noted potential dangers including contamination of groundwater, air pollution, surface spills, increased

Field survey of health perception and complaints of Pennsylvania residents in the Marcellus Shale region. *International Journal of Environmental Research and Public Health*, 11(6), 6517-6527. doi: 10.3390/ijerph110606517

truck traffic, noise pollution, occupational health hazards, and the generation of greenhouse gases. It also noted that proximity of potential fracking sites to human habitation should give regulators pause and called for a health impact assessment and study of long-term impacts.¹⁴⁶⁸ Responding to the report, the Environmental Health Association of Nova Scotia applauded the go-slow approach and called for a 10-year moratorium on fracking.¹⁴⁶⁹

- May 29, 2014 – In New York State, more than 250 medical organizations and health professionals released a letter detailing emerging trends in the data on fracking that show significant risk to public health, air quality, and water, as well as other impacts. With signatories including the American Academy of Pediatrics, District II, the American Lung Association in New York, Physicians for Social Responsibility, and many leading researchers examining the impacts of fracking, they wrote, “The totality of the science — which now encompasses hundreds of peer-reviewed studies and hundreds of additional reports and case examples—shows that permitting fracking in New York would pose significant threats to the air, water, health and safety of New Yorkers.”^{1470, 1471}
- May 9, 2014 – In a peer-reviewed analysis, leading toxicologists outlined some of the potential harm and uncertainty relating to the toxicity of the chemical and physical agents associated with fracking, individually and in combination. While acknowledging the need for more research and greater involvement of toxicologists, they noted the potential for surface and groundwater contamination from fracking, growing concerns about air pollution particularly in the aggregate, and occupational exposures that pose a series of potential hazards to worker health.^{1472, 1473}
- May 1, 2014 – A 292-page report from a panel of top Canadian scientists urged caution on fracking, noting that it poses “the possibility of major adverse impacts on people and ecosystems” and that significantly more study is necessary to understand the full extent of the risks and impacts.¹⁴⁷⁴ The *Financial Post* reported that the panel of experts “found

significant uncertainty on the risks to the environment and human health, which include possible contamination of ground water as well as exposure to poorly understood combinations of chemicals.”¹⁴⁷⁵

- April 30, 2014 – Medical professionals spoke out on the dearth of public health information collected and lack of long-term study five years into Pennsylvania’s fracking boom. Walter Tsou, MD, MPH, past president of the American Public Health Association and former Health Commissioner of Philadelphia commented, “That kind of study from a rigorous scientific perspective has never been done.” Other experts added, “There has been more health research involving fracking in recent years, but every study seems to consider a different aspect, and ... there is no coordination.”¹⁴⁷⁶
- April 17, 2014 – In the preeminent *British Medical Journal*, authors of a commentary, including an endocrinologist and a professor of clinical public health, wrote, “Rigorous, quantitative epidemiological research is needed to assess the risks to public health, and data are just starting to emerge. As investigations of shale gas extraction in the US have continually suggested, assurances of safety are no proxy for adequate protection.”¹⁴⁷⁷
- April 15, 2014 – The *Canadian Medical Association Journal* reported on the increasing legitimacy of concerns about fracking on health: “While scientists and area residents have been sounding the alarm about the health impacts of shale gas drilling for years, recent studies, a legal decision and public health advocates are bringing greater legitimacy to concerns.”¹⁴⁷⁸
- March 3, 2014 – In the *Medical Journal of Australia*, researchers and a physician published a strongly worded statement, “Harms unknown: health uncertainties cast doubt on the role of unconventional gas in Australia’s energy future.” They cited knowledge to date on air, water, and soil pollution, and expressed concern about “environmental, social and psychological factors that have more indirect effects on health, and important social justice implications” yet to be understood. They wrote in summary:

The uncertainties surrounding the health implications of unconventional gas, when considered together with doubts surrounding its greenhouse gas profile and cost, weigh heavily against proceeding with proposed future developments. While the health effects associated with fracturing chemicals have attracted considerable

public attention, risks posed by wastewater, community disruption and the interaction between exposures are of also of concern.¹⁴⁷⁹

- March 1, 2014 – In the prestigious British medical journal *The Lancet*, researchers summarized workshops and research about the health impacts of fracking, noting that the scientific study on the health impacts of fracking is “in its infancy.” Nevertheless, the existing evidence suggests, said these researchers, that health risks posed by fracking exceed those posed by conventional oil and gas wells due to the sheer number and density of well pads being developed, their proximity to densely populated areas, and the need to transport and store large volumes of materials.¹⁴⁸⁰
- February 24, 2014 – In a review of the health effects of unconventional natural gas extraction published in the journal *Environmental Science & Technology*, leading researchers identified a range of impacts and exposure pathways that can be detrimental to human health. Noting how fracking disrupts communities, the review states, “For communities near development and production sites the major stressors are air pollutants, ground and surface water contamination, truck traffic and noise pollution, accidents and malfunctions, and psychosocial stress associated with community change.” They concluded, “Overall, the current scientific literature suggests that there are both substantial public concerns and major uncertainties to address.”¹⁴⁸¹
- August 30, 2013 – A summary of a 2012 workshop by the Institute of Medicine Roundtable on Environmental Health Sciences, Research, and Medicine featured various experts who discussed health and environmental concerns about fracking and the need for more research. The report in summary of the workshop stated, “The governmental public health system, which retains primary responsibility for health, was not an early participant in discussions about shale gas extraction; thus public health is lacking critical information about environmental health impacts of these technologies and is limited in its ability to address concerns raised by regulators at the federal and state levels, communities, and workers employed in the shale gas extraction industry.”¹⁴⁸²
- June 2013 – A group of three nursing professors published a cautionary review questioning the rollout of new shale-based energy practices at a time when, “anecdotal reports make clear that the removal of fossil fuels from the earth directly affects human health.” Although the results of longterm studies are not yet available, the authors point to emerging evidence for negative human and ecologic health effects of fracking.

Furthermore, they continue, “sufficient evidence has been presented to the [American Nurses Association], the American Public Health Association, and the American Medical Association’s Resident and Fellow Section to result in a call for a moratorium on the issuance of new fracking permits nationally.” They urge nurses to contribute to keeping health issues “front and center as we address national energy needs and policies.”¹⁴⁸³

- April 22, 2013 – In one of the first peer-reviewed nursing articles summarizing the known health and community risks of fracking, Professor Margaret Rafferty, Chair of the Department of Nursing at New York City College of Technology wrote, “Any initiation or further expansion of unconventional gas drilling must be preceded by a comprehensive Health Impact Assessment (HIA).”¹⁴⁸⁴
- May 10, 2011 – In the *American Journal of Public Health*, two medical experts cautioned that fracking “poses a threat to the environment and to the public's health. There is evidence that many of the chemicals used in fracking can damage the lungs, liver, kidneys, blood, and brain.” The authors urged that it would be prudent to invoke the precautionary principle in order to protect public health and the environment.¹⁴⁸⁵

EXHIBIT 17

Existing scientific literature on setback distances from oil and gas development sites

Nicole J. Wong, MPH

November 2017 (revised)

Background: Need for an LA Relevant Setback

The current body of peer-reviewed scientific literature has a small but growing set of studies investigating the relationship between the proximity of modern oil and gas extraction nearby communities and health impacts. The published studies that have examined this relationship have considered health outcomes, exposure to toxic health risks, and discussed whether current setback requirements in various states are adequate to ensure the health and safety of people who live, work, play, and learn near these facilities. These studies were conducted primarily in lower population density communities and states. Yet, the majority of these studies find a positive correlation between distance of a home from an active oil or gas well and adverse health outcomes. The closer people live to oil and gas wells, the more likely they will be exposed to toxic air contaminants and the more elevated their risk of associated health effects.¹ Most of these distances are measured at a half-mile to a mile (See Table 2). Distances in Los Angeles are much closer. No peer-reviewed studies to date have investigated the relationship between the proximity of oil and gas development and health outcomes in California, nor have any studied this issue in the U.S. urban context. In Los Angeles alone, about 1.7 million people live within 1 mile of an active oil or gas well, and of that group, more than 32,000 people live within 100 m (about 328 feet) of an oil or gas well.²

Overview of Report Contents

A total of 14 studies and publications were considered for this report that investigated the health and quality of life impacts and exposures of unconventional natural gas development proximate to residences. Of the 14 studies and publications, 6 considered the distance of an active well to place of residence (Table 1), while the remaining 4 considered the concentration of wells proximate to residences (Table 2). Four of the publications are studies and non-peer reviewed reports that have setback recommendations or relevant considerations for a safe setback margin (included in Table 1). The distances considered in this report range in setback recommendations and findings from 1,500 to 6,600 feet. Among the peer-reviewed studies that specified where samples and data were collected, the average population density was about 150 people per square mile. To compare, the population density for the City of Los Angeles is about 50 times greater at 8,092.3 people per square mile. In neighborhoods like South Los Angeles that is home to several active oil drilling sites, the population densities are up to more than 20,000 people per square mile.³ The population density in South Los Angeles is about **133 times greater** than those of the populations investigated in the existing literature. Table 1 lays out the peer-reviewed studies included in this report, ordered by the safe setback distance each study considered. Advocacy groups in Los Angeles have called for a 2,500-foot setback law to protect the health and safety of nearby residents.

The population density in South Los Angeles is about **133 times greater** than the populations investigated in the existing literature.

Based on the current available research, a 2,500-foot setback recommendation is on the lower end

of the range of distances where research has determined harmful health and quality of life impacts of toxic emissions and exposures.

Oil and Gas Extraction Methods

During much of the early and mid 1900's, conventional methods of extracting oil depleted most of the oil fields throughout the country. In Los Angeles, only 10% of oil field reservoirs can be recovered by conventional means.² Now, in order to access resources that are deeper or more difficult to recover than those that have been recovered historically, oil industry has pursued new technologies in "unconventional" or "enhanced oil recovery" methods.^{2,5} These methods include steam, water, and/or chemical injection, hydraulic fracturing, acidization, and gravel packing.

Although the existing research has primarily focused on health impacts and toxic emissions from unconventional natural gas development, many of the same chemicals of concern used in so-called unconventional activities are used in routine activities such as well maintenance, well-completion, or rework on both conventional oil and natural gas wells.⁶ There are many applications of hazardous chemicals in oil and gas development, and in fact the routine operational chemical use data is less available than that for unconventional chemical use activities.⁶

In Los Angeles, many of the extraction facilities utilize unconventional techniques, such as acidizing with hydrochloric and hydrofluoric acid, directional drilling, and gravel packing which involves use of tons of carcinogenic silica sand. Many of the oil fields in Los Angeles produce both oil and gas at a relatively equal ratio. Among the top ten producing oil fields in the City of Los Angeles, which include Beverly Hills, Wilmington, and Las Cienegas oil fields, the ratio of gas to oil production is about 0.91.⁷ Therefore, the existing research in other parts of the country holds relevance for the nature of oil and gas extraction in Los Angeles.

Health and Quality of Life Impacts

The consequences to health from oil and gas activity investigated in the reviewed studies include birth outcomes, asthma, other respiratory and dermal impacts, pediatric sub-chronic non-cancer and chronic hazard indices, unhealthy noise levels, and various associated health symptoms. Among the existing research, the greatest distance to oil and gas activity investigated was 2 km (6,561 feet) where exposure to hydrogen sulfide combined with VOCs were detected.⁸ The shortest distance measurement studied was 1,500 feet and this study found significantly more reports of health symptoms in households within 1,500 feet of an active well. The health symptoms included throat irritation, sinus problems, nasal irritation, eye burning, severe headaches, loss of sense of smell, persistent cough, frequent nose bleeds, swollen painful joints.⁹ Rabinowitz, et al. (2015) found an increased number of reported upper respiratory symptoms and skin conditions among residents who lived less than 1 km (3,280 feet) from an active well when compared with residents who lived more than 2 km (6,561 feet) from an active well.¹⁰ McKenzie, et al. (2012) found elevated risk of health effects from natural gas development for residents living less than half a mile from wells. They primarily considered the subchronic non-cancer hazard index, which was primarily driven up by exposure to trimethylbenzenes, xylenes, and aliphatic hydrocarbons, and chronic hazard index measurements, which were driven up by benzene exposure.¹¹

Another dimension of health impacts related to oil and gas development is noise levels. Boyle, et al. (2017) conducted a pilot study investigating the 24-hour noise levels of a compressor station relative to

residential homes both indoors and outdoors.¹² His study determined that homes up to 600m away (about 1,968 feet) experienced outdoor noise levels that exceeded the U.S. Environmental Protection Agency's recommended limit of 55 dBA 100% of the time.¹² In addition to these punctuated periods of noise, the regular day-to-day operations at the site cause what has been described as "buzzing" throughout the night makes it difficult to sleep. Recent studies have increasingly focused on "non-auditory" effects of noise on health including annoyance, sleep disturbance, daytime sleepiness, hypertension, cardiovascular disease, and diminished cognitive performance in school children.¹³ Many residents living in close proximity to oil and gas development sites in Los Angeles routinely complain of noise from routine operations.

Air Quality and Toxic Exposure

Three of the studies investigated levels of volatile organic compounds (VOCs) and endocrine disrupting chemicals that exceeded regulatory agency minimum standards. Haley, et al. (2016) discussed how exposures of hydrogen sulfide combined with VOCs could produce potentially new harmful exposures that could be detected at distances up to 2 km (about 6,561 feet).⁸ Macey, et al. (2014) investigated several jurisdictions with setback regulations for oil and gas operations and conducted air monitoring sampling to examine if the setbacks were adequate.¹⁴ The findings revealed high concentrations of carcinogenic VOCs at distances greater than the setback regulations, including formaldehyde at 2,591 feet and benzene up to 885 feet away from wells. The study also discussed how health-based risk levels that most regulatory agencies rely on for setting limits on air emissions are very limited in providing a sense of the human health impacts.¹⁴ The risk level standards do not account for more vulnerable subpopulations like children and the elderly. Additionally, the number of compounds that are required for monitoring and toxicity reporting is relatively small when considering the vast number of chemicals required for oil and gas operations.¹⁴ Kassotis, et al. (2014) found elevated levels of endocrine disrupting chemicals in water sources 1 mile away from oil and gas operations with known spills or incidences.¹⁵ The study noted that near one of the investigated facilities contaminated by endocrine disrupting chemicals (EDCs), some of the animals in the area were no longer producing live offspring.

The findings revealed high concentrations of VOCs at greater distances than the setback regulations, including formaldehyde at 2,591 feet and benzene up to 885 feet away from wells.

Explosion Risk and Hazards

Haley, et al. (2016) considered the minimum distance that might be required in case of a blow-out or explosion event by investigating historical evacuation data.⁸ For example, an explosion in the Barnett Shale in northern Texas produced a 750-foot burn crater.¹⁶ Their findings determined that the average evacuation zone for such incidences is 0.8 miles, or 4,224 feet. A blowout in Wyoming County, PA required a 1,500 foot evacuation zone, which required the evacuation of only 3 families.¹⁷ Considering that in Wyoming County the population density was only 71.2 people per square mile¹⁸¹⁶ compared to a densely populated neighborhood in South Los Angeles with a population density of over 20,000, if a similar event were to happen, the same distance of 1,500 feet would require evacuation of 100,743 people. A very recent example of natural gas pipeline explosion accident comes from rural Colorado. On April 17, 2017, a one-inch abandoned pipeline exploded under a home in Colorado, leveled the house,

killed two people and badly burned a third person. The gas well head was located just 178 feet from the home.¹⁹

Dense Population of the City of Los Angeles and Close Proximity to Oil and Gas Facilities Magnifies Health and Safety Risks

Four studies investigated the relationship between health outcomes and the number of wells within a certain radius of residential homes (Table 3). The studies were concerned with birth outcomes and childhood leukemia and were conducted in Pennsylvania and Colorado. The density measures ranged from 3.36 – 125 wells per square mile. To compare to Los Angeles, the four extraction facilities in South Los Angeles that extract from the Las Cienegas oil field, the 2nd largest gas producing field in Los Angeles, each have 22 to 36 oil and gas wells operating less than 100 feet from residential homes. The Inglewood oil field has over 1000 wells operating well within 1 mile of residential homes, recreation parks, and other sensitive land uses.

The studies that investigated poor birth outcomes found that mothers in the sampling population who lived near the highest density of active wells were 1.3 more likely to give birth to a child who had congenital heart defects (CHD) and 2 times more likely to give birth to a child with neural tube defects (NTD),²² higher incidences of LBW and SGA,²³ and increased rate of preterm birth.²⁴ McKenzie, et al. (2017) found that increased well density was associated with increased risk for acute lymphocytic leukemia in people ages 5-24.²⁵

Delphi Technique

In addition to peer review studies, a consortium of experts in environmental studies and public health have also assessed and considered policy recommendations to address the health and safety consequences of close proximity to oil and gas development. The Environmental Health Project (EHP) is a public health organization that utilized the Delphi Technique to arrive at an expert consensus on an appropriate setback distance for unconventional oil and gas development from human activity.²¹ “The

...89% participant agreement that **1 to 1.25-mile distance** from unconventional oil and gas development is an acceptable minimum.

Delphi is an accepted method for reaching convergence of expert opinion about a specific topic,” and in this study, consensus was defined as 70% agreement of panelists. The process resulted in an 89% participant agreement that 1 to 1.25-mile distance (6,600 feet) from unconventional oil and gas development is an acceptable minimum to protect human health. Additionally, the study recommends greater setback distances for settings where vulnerable subpopulations might gather, such as schools, day care centers, and

hospitals.

Existing setback laws

It is clear that throughout the scientific literature that researchers agree the existing setback laws in various jurisdictions throughout the U.S. are inadequate to protect the health and safety of residents who live, work, and play near oil and gas operations. Existing setback laws range from 150 to 1,500 feet. States like Arkansas,

...**existing setback laws** in various jurisdictions throughout the U.S. **are inadequate** to protect the health and safety of residents who live, work, and play nearby oil and gas operations.

Colorado, and Ohio have varying setback distances from different sensitive land uses.^{8,14} Pennsylvania and Texas have state level setback laws for any oil and gas operations near residential land use. Several municipalities in Denton County, Texas, have enforced stronger setback laws. In response to override these municipalities, the Texas state legislature subsequently passed HB40 which preempts regulation of oil and gas operations by municipalities. Haley, et al. (2016) determined that based on historical catastrophic events, thermal modeling, vapor cloud modeling, and air pollution data, these existing setbacks laws are not sufficient to protect potential risks and threats to human health from hydraulic fracturing operations.⁸ Macey, et al. (2014) considered the concentration of VOCs in five different states and determined that the setbacks in those states were inadequate to prevent exposure to formaldehyde and benzene.¹⁴ Majority of the established setback laws were typically decided by negotiations between stakeholders, like residents and policymakers, and not supported by scientific, empirical data.²³ The state of Maryland is one example of a jurisdiction that scientifically investigated the health and safety impact of oil and gas operations. In July of 2014, the University of Maryland School of Public Health conducted another study that focused on public health impacts.²⁶ Among the 52 recommendations that resulted from the investigation, the researchers recommended a minimum 2,000-foot setback between dwellings and well pads and non-electric motor compressor stations. In 2017, Maryland became the second state in the country to ban hydraulic fracturing.²⁷

Conclusions

While few studies have investigated the relationship between the proximity of oil and gas operations and human health impacts, this body of literature does highlight a clear public health concern and that existing setback laws are not adequately protecting public health and safety. **The growing body of scientific literature recognizes that a setback distance between oil and gas operations and locations where people live, work, play, and learn are necessary to protect human health and safety. Setbacks are especially crucial to protect vulnerable populations, such as children, elderly, and the chronically ill or disabled.** The 2,500-foot setback recommendation incorporates recognition of Los Angeles' population density and the vulnerability of residents, schoolchildren, and the elderly from health hazards and possible disasters related to oil development. The current literature has identified that existing laws are not adequate for low density, rural communities. This finding underscores the need for a stronger setback in Los Angeles' densely populated urban environment. Many of the impacted communities are in close proximity to a large number of wells and other oil and gas development facilities and are already overburdened by exposure to cumulative environmental health impacts from other industrial and transportation sources. These marginalized communities have long endured environmental injustice. **The scientific literature and published reports make a strong case for a far more protective health and safety setback for the City of Los Angeles than currently exists in other jurisdictions, and creates a substantial basis for the 2,500-foot setback proposed by community advocates.**

Table 1. Comparison of studies and reports by distance to active oil and gas wells with consideration to population density.

Blue shaded rows are non-peer reviewed reports. Orange shaded rows are peer reviewed publications that have relevant setback considerations or recommendations.

EXHIBIT 18

2006 ANNUAL REPORT OF THE STATE OIL & GAS SUPERVISOR

California Department of Conservation
Division of Oil, Gas, & Geothermal Resources

dropped slightly from 1,907 in 2006 to 1,895 beginning 2007.

DRILLING ACTIVITY Drilling activity in the district decreased slightly from 2005 levels. Twenty-six wells were drilled or redrilled in 2006, compared with 30 in 2005. The following operators drilled/redrilled wells: Aera Energy LLC - 10 wells in the Ventura field; Berry Petroleum Co. - 7 wells in the Placerita field; Mirada Petroleum, Inc. - 1 well in the Ojai field; Renaissance Petroleum, Inc. - 3 wells in the Cabrillo field; Southern California Gas Co. - 4 wells in the Aliso Canyon field; Vaquero Energy, Inc. - 1 well in the Sespe field.

ACQUISITION OF VINTAGE PETROLEUM WELLS BY OCCIDENTAL PETROLEUM COMPANY In 2006, all the wells operated by Vintage Petroleum Inc. in District 2 were acquired by Vintage Production California LLC (VPC), a subsidiary of Occidental Petroleum Corporation. In addition, VPC acquired Plains Exploration and Production Co. operations in the Oxnard, Saticoy, South Mountain and Pacoima oil fields and the Newhall-Potrero oil field formerly operated by Medallion California Properties Company. Through these acquisitions, VPC owns 1,797 wells in 24 of the 45 active fields in District 2. In 2006, VPC initiated a program to upgrade existing facilities and dismantle out-of-service facilities, with work beginning in the San Miguelito and Rincon oil fields.

ABANDONMENT OF WELL "OJAI" 36 On March 3, 2006, immediately following a seismic event along

the San Cayetana fault in the Sespe oil field, idle-well "Ojai" 36, located approximately five miles west along this same fault zone in the Sisar Creek Area of the Ojai oil field, began to flow water at a rate of five barrels per minute. Well records indicated the well penetrated a fault and had encountered a high-pressure water sand. The operator, VPC, contracted with international well-control specialists Boots and Coots to begin emergency operations to secure the well site and bring the well under control. Division staff were on location daily to witness operations. The well was eventually killed with 20 pound-per-gallon mud and permanently plugged and abandoned by May 1st at a cost of approximately \$4 million (Photos 1 and 2).

ABANDONMENT OF BARSDDALE OIL FIELD WELLS At the request of the Division, VPC permanently plugged and abandoned 15 long-term idle wells on the "Acorn" and "Bardsdale-Bell" leases in the Bardsdale oil field. Many of these wells were discovered following the October 2003 fires when surrounding dense brush was consumed. The "Acorn" lease was discovered in 1894 and the "Bardsdale-Bell" lease in 1909, with all wells drilled using cable tool rigs and equipment (Photo 3). Most of the well locations were along steep hillsides, which made access extremely challenging and required a significant amount of grading to build locations adequate to accommodate the necessary abandonment equipment (Photos 4 – 7). Most of the wells required two to three times the theoretical volumes of cement to bring cement to surface, probably due to the antiquated landed casing completions.

Photo 1. Well "Ojai" 36. During killing operations, vacuum trucks removed water flowing from the well until kill mud could be injected to help secure the well before abandonment operations could begin. *Photo by D. Kahler.*

Executive Summary

This report analyzes the earthquake risks associated with an increase in wastewater injection that would result from an expansion of fracking and other unconventional oil production in California's Monterey Shale, including:

- the demonstrated connection between the injection of oil and gas wastewater and induced earthquakes,
- significant gaps in current science and inability of regulators to protect Californians from the dangers associated with these quakes, and
- proximity of many active California wastewater injection wells to active faults and major population centers.

To graphically illustrate the risks, the report includes maps from an online interactive tool developed by the FracTracker Alliance, which show the current extent of oil and gas development, including active wastewater injection wells, fracked and acidized wells, fault lines, and communities.

Key Findings:

1. A majority of California's active oil and gas wastewater injection wells are close to faults.

Our analysis shows that 54 percent of California's 1,553 active and new wastewater injection wells are within 10 miles of a recently active fault (active in the past 200 years), 23 percent are within 5 miles, and 6 percent are within 1 mile. Because the distance from a wastewater injection well to a fault is a key risk factor influencing whether a well may induce an earthquake, these findings raise significant concerns.

| Distance of California's Active/New Wastewater Injection Wells to Recently Active Faults | |
|------------------------------------------------------------------------------------------|-----------------------------------|
| NUMBER OF ACTIVE/NEW WELLS (PERCENT) | DISTANCE TO RECENTLY ACTIVE FAULT |
| 87 wells (6%) | Within 1 mile |
| 350 wells (23%) | Within 5 miles |
| 834 wells (54%) | Within 10 miles |

2. Millions of Californians live in areas at risk for induced earthquakes. Some of California's major population centers, such as Los Angeles and Bakersfield, are located in regions where high densities of wastewater injection wells are operating very close to active faults.

- 3. Research and monitoring are dangerously inadequate.** No studies to date have evaluated the increased risk of induced earthquakes from California’s existing wastewater injection wells. There are fundamental knowledge gaps in understanding the risks of induced seismicity from these wells.
- 4. Regulations do not protect Californians from the risk of induced earthquakes.** California has no plan to safeguard its residents from the risks of earthquakes induced by Class II injection wells or oil and gas production. Due to significant knowledge gaps, California’s Division of Oil, Gas, and Geothermal Resources (DOGGR) cannot safely regulate the risk of induced seismicity from oil and gas production and wastewater disposal.
- 5. Oil industry wastewater disposal poses unacceptable risks.** In light of the known environmental and health risks from drilling, well stimulation and wastewater disposal, the link between wastewater injection wells and earthquakes in other states, the potential for a massive expansion of drilling and wastewater production in the Monterey Shale, and the gaps in scientific knowledge regarding induced seismicity, the best way to protect Californians is to halt hydraulic fracturing, acidizing, and other unconventional oil and gas recovery techniques.

In sum, the findings highlight the lack of assurance that fracking and the injection of oil and gas wastewater can be conducted safely, and demonstrate the need for a halt to fracking, acidizing, and other forms of well stimulation.

This report is necessary because California’s oil industry may be on the verge of rapidly expanding unconventional oil production of the Monterey Shale, a vast shale oil deposit in the San Joaquin Valley, parts of the Central Coast, and the Los Angeles basin that underlies many communities, important wildlife habitat, and some of the nation’s richest farmland.

Oil and gas production results in billions of gallons of contaminated wastewater that is often disposed of in underground injection wells. In many parts of the eastern and central United States where fracking and wastewater injection have boomed, earthquake activity has increased dramatically. Some regions have experienced a 10-fold increase in earthquake activity. A growing body of research has linked wastewater injection wells to increased earthquake activity, including earthquakes that have damaged homes and infrastructure and caused human injuries. Extracting the oil in the Monterey Shale could produce almost 9 trillion gallons of wastewater.

California is uniquely vulnerable to seismic events, with more citizens and infrastructure at risk from earthquakes than any other U.S. state. Seven of the ten U.S. metropolitan areas with the highest estimated annualized losses from earthquake damage are located in the Golden State. An increase in damaging seismic activity would be devastating to California and its economy.

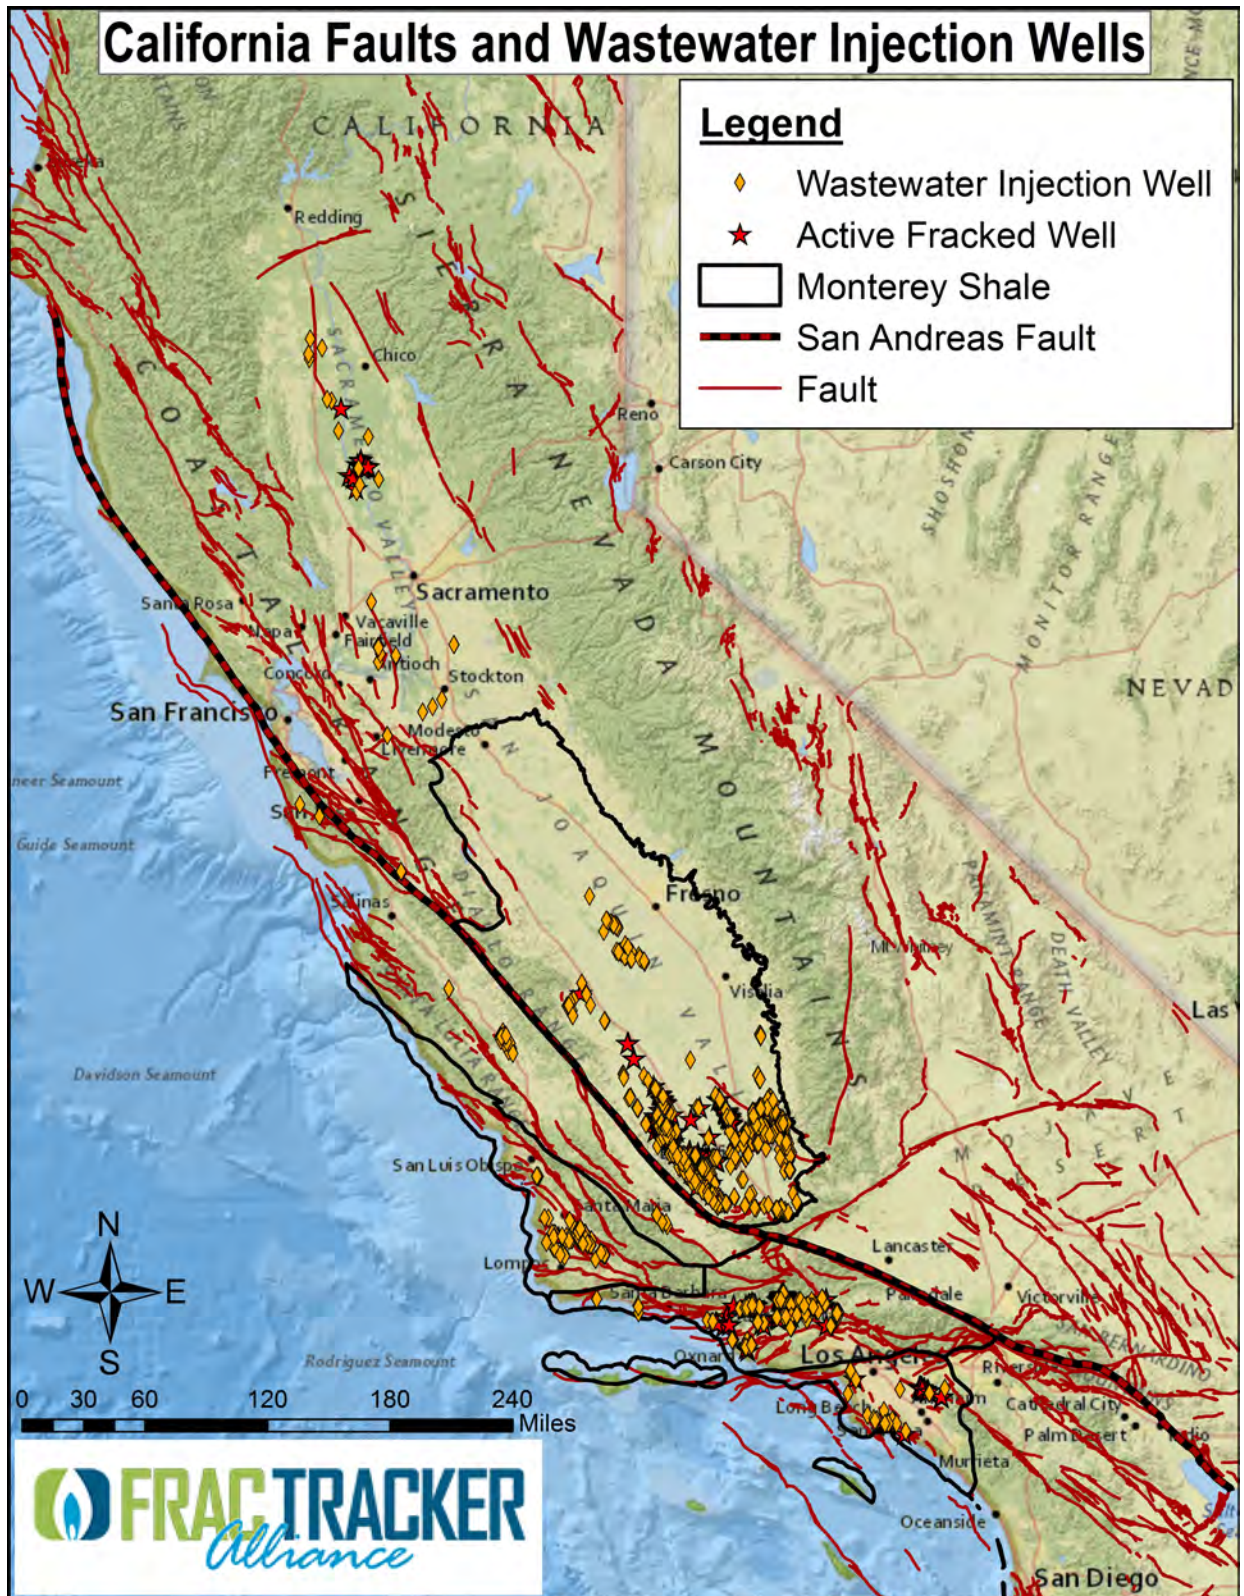

FIGURE 1: California's Faults and Wastewater Injection Wells

Fracking, Wastewater Injection Wells, and Increased Earthquake Risks

1. Fracking and acidizing produce large volumes of contaminated wastewater.

The development of unconventional oil and gas recovery techniques, such as hydraulic fracturing and acidizing, has allowed for a rapid expansion of shale oil and gas development across many parts of the United States. Hydraulic fracturing, or fracking, is a well stimulation technique that releases oil and gas from relatively impermeable formations, such as shale and tight sands, allowing for the extraction of previously unreachable hydrocarbons. Fracking typically involves pumping high volumes of water, sand, and chemicals at high pressures into the rock formation, causing it to crack and release oil and gas.¹

Although fracking has been done in the U.S. for many years, recent developments, such as directional and horizontal drilling and new chemical fluid mixtures, have facilitated an increase of drilling in previously uneconomic geologic formations.

Acidizing, another well stimulation technique, involves the injection of hydrochloric and/or hydrofluoric acids, along with some of the same fluids used for fracking.² These chemicals modify the permeability of a geologic formation, allowing increased hydrocarbon flow. In California, acidizing may be the well stimulation treatment of choice for the oil and gas industry to access the Monterey Shale, due to the highly fractured geology of the state.³

Hydraulic fracturing, acidizing and other unconventional well stimulation methods create large quantities of wastewater — called flowback and produced water — that contain contaminants which can reach toxic concentrations. Flowback is the fluid that returns to the surface after fracturing or acidizing is completed, but before oil and gas is recovered from the well. Produced water is primarily composed of the formation fluid that comes to the surface once production of oil and gas has begun. Produced water is associated with all forms of oil and gas production, regardless of the well stimulation technique.

Both flowback and produced water can contain chemicals from the fracking fluid and the fluids rising from deep in the rock formation, which can be harmful to human health. An estimated 15 to 100 percent of fracking fluids return to the surface as wastewater.⁴ More than 75 percent of the chemical additives in fracking fluids can affect important organs, and 25 percent can cause cancer.⁵ Flowback and produced water are typically very saline and can contain heavy metals such as lead, organic contaminants such as benzene and toluene, and naturally occurring radioactive materials from deep in the formation,⁶ which makes treatment and recycling difficult.

Recent estimates report that flowback volumes can range between 420,000 gallons to more than 2.5 million gallons per fracking event, depending on the characteristics of the formation, the amount of fluid injected, and the type of hydrocarbon being extracted.⁷ Produced water can reach millions of gallons over the lifetime of the well.⁸ In California, oil and gas wells averaged approximately 2.3 million gallons of wastewater per well in 2011.⁹

2. Underground injection wells are the most common method for disposing of oil and gas wastewater in California and many other parts of the U.S.

The wastewater produced during oil and gas extraction is either disposed of or reused for additional oil and gas extraction in a process called “secondary recovery” or “enhanced oil recovery (EOR).” In California and many other parts of the country, the most common wastewater disposal method is trucking or piping the wastewater for injection into deep wastewater injection wells, drilled into porous rock thousands of feet underground.¹⁰ These wastewater injection wells are categorized as Class II Underground Injection Wells by the U.S. Environmental Protection Agency (EPA), which oversees their regulation under the Safe Drinking Water Act’s (SDWA) Underground Injection Control (UIC) Program.¹¹ In California, the Division of Oil Gas and Geothermal Resources (DOGGR) received primacy to directly regulate the state’s Class II underground injection wells in 1982.¹²

There are about 30,000 Class II wastewater injection wells in operation in the U.S. that are used for wastewater disposal from oil and gas production.¹³ Texas leads the nation with about 7,500 active wastewater injection wells,¹⁴ followed by Oklahoma with an estimated 4,400 active wells.¹⁵

California has an estimated 2,583 wastewater injection wells, of which 1,553 are currently active.¹⁶ Wastewater injection wells are located throughout the state, from the Chico area in northern California, to Kern County in the Southern San Joaquin Valley, to Los Angeles in the south, and even offshore near Santa Barbara.¹⁷

California’s oil and gas fields produce billions of gallons of contaminated wastewater each year that must be managed — about 15 times more wastewater than oil.¹⁸ In 2012 alone, California’s oil and gas industry produced an estimated 124 billion gallons of wastewater.¹⁹ Much of this wastewater is permanently disposed of in wastewater injection wells. According to the most recent data available from the U.S. Department of Energy, in 2007 California’s oil and gas industry disposed of 22 percent of the wastewater it produced into injection wells, totaling more than 23 billion gallons²⁰ — equivalent to about 35,500 Olympic-sized swimming pools. About 69 percent of the wastewater was reused for enhanced recovery,²¹ and small amounts are disposed of in unlined percolation ponds, lined evaporation ponds, sewer systems, and surface waters.²²

The amount of wastewater being disposed of in injection wells has skyrocketed in states where fracking has proliferated in recent years.

In 2012 alone, California’s oil and gas industry produced an estimated 124 billion gallons of wastewater.

In Texas, for example, the amount of wastewater injected into disposal wells increased from 1.9 billion gallons in 2005 to nearly 147 billion gallons in 2011 — a 76-fold increase.²³

California's oil and gas industry may be on the verge of rapidly expanding unconventional oil production in the Monterey Shale, a vast shale deposit in the San Joaquin Valley, parts of the Central Coast and the Los Angeles basin, which holds an estimated 13.7 billion barrels of technically recoverable shale oil.²⁴ If the oil and gas industry develops the Monterey Shale, the production of wastewater and demand for wastewater injection wells are likely to increase substantially. For example, based on the historically reported ratio of 15 times more wastewater than oil produced in California, extracting the Monterey Shale's estimated 13.7 billion barrels of recoverable oil could produce 8.6 trillion gallons (205.5 billion barrels) of wastewater — enough to fill almost 13 million Olympic-sized swimming pools.

3. Scientists have long documented that wastewater injection wells can induce earthquakes.

The underground injection of wastewater has long been documented to induce earthquakes. Wastewater injected into rock formations can build up significant pressure depending on the volume of wastewater, rate of injection, and the permeability of the rock. This pressure build-up can induce an earthquake if the pressure is relayed to a fault that is already stressed and close to failure. The pressure can reduce the natural friction on the fault enough to cause it to slip and trigger an earthquake.²⁵ The larger the fault, the larger the magnitude of earthquakes it can host.²⁶

As early as the 1960s, scientists began documenting seismic activity from the injection of large volumes of fluids underground.²⁷ One of the first recorded cases of human-induced earthquakes due to underground fluid injection occurred in 1961, when the U.S. Army began disposing of millions of gallons of liquid hazardous waste 12,000 feet below the surface at the Rocky Mountain Arsenal near Denver, Colorado. This injection spurred more than 1,500 earthquakes over a five-year period in an area not known for active seismicity. It culminated in three earthquakes of magnitudes 5.0 to 5.5 more than a year after injection ceased, the largest of which caused more than \$500,000 in damages. Geologists discovered that the Army well had been drilled into an unknown fault. This example, as well as two other well-studied fluid injection projects — at Rangely, Colorado, in the 1970s and Paradox Valley, Colorado, in the 1990s — established that wastewater injection wells could induce earthquakes large enough to cause significant damage.²⁸

4. Wastewater injection wells have induced felt and damaging earthquakes of magnitudes 4 and 5 in regions where fracking has proliferated.

In many areas of the U.S. where fracking has proliferated, earthquake activity has increased dramatically. As scientists begin to investigate the causes of these earthquake swarms, a growing number of studies have attributed some of this increased earthquake activity, and some of the largest earthquakes, to the underground injection of oil and gas wastewater in these regions.²⁹

Within the Midwestern and Eastern U.S., the number of recorded earthquakes began to increase in 2003, rising dramatically after 2009.³⁰ In total, an average of 100 earthquakes per year of magnitude³¹ 3 (M3) or larger struck between 2010 and 2012, compared with only 21 per year between 1967 and 2000.³² States experiencing elevated levels of earthquake activity in parallel with booms in unconventional oil and gas development include Oklahoma, Texas, Colorado, New Mexico, Arkansas, Ohio, and West Virginia.³³

Earthquakes of M3 to M5 have been scientifically linked to wastewater injection wells in at least six states: Oklahoma, Texas, Colorado, New Mexico, Arkansas, and Ohio. The largest of these was a M5.7 earthquake near Prague, Oklahoma, outside of Oklahoma City which was the biggest in the state's history. It destroyed 14 homes, damaged infrastructure and numerous buildings, and injured two people.³⁴

Other large earthquakes attributed to wastewater injection include a M4.8 in Texas, M5.3 in Colorado, M4.7 in Arkansas, and M3.9 in Ohio, as summarized by state below:

Oklahoma: Oklahoma's earthquake activity has increased dramatically since 2009, with the increase linked to wastewater injection wells.³⁵ The state has been hit by more than 200 earthquakes of M3 or larger since 2009 — about 40 per year — compared to 1 to 3 a year between 1975 and 2008.³⁶ According to the U.S. Geological Survey (USGS), the likelihood of an earthquake in central Oklahoma has increased by a factor of 10.³⁷ These earthquake swarms are striking in populated areas, culminating with the largest earthquake ever recorded in the state — the damaging M5.7 earthquake near Prague outside Oklahoma City in 2011, which scientists have linked to injection wells.³⁸ In October 2013, the USGS and Oklahoma Geological Survey (OGS) warned that the "earthquake swarm" around Prague and Oklahoma City has increased hazards for city and rural residents, and stated that wastewater injection wells may be a "contributing factor."³⁹ This warning caused the State Insurance Commissioner to recommend that Oklahoma residents buy earthquake insurance.⁴⁰ Recent earthquake swarms have also hit near Marietta in southern Oklahoma and Enid to the north, with these swarms also thought to be linked to wastewater injection wells.⁴¹

Earthquake activity has increased dramatically in many areas of the U.S. where fracking has proliferated.

Texas: Several regions of Texas have experienced increased earthquake activity near wastewater injection wells in areas where no previous seismic activity has been recorded. In regions near Dallas-Ft. Worth, Cleburne, and Timpson, scientists have linked increased earthquake activity to wastewater injection wells.⁴² Timpson, Texas, has been struck by a series of damaging earthquakes, including the largest ever recorded in eastern Texas — a M4.8 in May 2012 which caused significant structural damage⁴³ — and M4.1 and M4.3 earthquakes in 2013.⁴⁴ In the heavily populated Dallas-Fort Worth region, scientists have attributed a series of small earthquakes in 2009 to wastewater injection.⁴⁵ Since 2009, the region has been hit by stronger earthquakes between M3 and M4.⁴⁶

Colorado/New Mexico: Earthquake activity has increased dramatically in the Raton Basin of southern Colorado and northern New Mexico, culminating in a M5.3 earthquake near Trinidad, Colorado, in August 2011, with increased seismicity being attributed to wastewater injection wells.⁴⁷ The number of earthquakes of M3 or greater increased from 0.16 per year in the 31-year period before injection, to 9.5 per year after injection began in 2001.

Arkansas: Earthquake activity in central Arkansas increased sharply in 2010 and 2011, when earthquake swarms hit near the towns of Guy and Greenbrier, close to injection wells, culminating in a M4.7 earthquake in February 2011.⁴⁸ After the first wastewater disposal well became operational in April 2009, the rate of $M \geq 2.5$ earthquakes skyrocketed, with one in 2007, two in 2008, 10 in 2009, 54 in 2010, and 157 in 2011. Scientists have determined that these swarms were likely induced by wastewater injection.⁴⁹

Ohio: The injection of wastewater into a deep well has been linked to a series of earthquakes in a previously earthquake-free region near Youngstown, Ohio.⁵⁰ More than 109 earthquakes occurred between January 2011 and February 2012, with a M3.9 earthquake striking on December 31, 2011.

This growing body of research demonstrates that injecting wastewater into underground disposal wells can induce earthquakes. These studies also illustrate what is currently known and unknown about the risks of induced earthquakes from wastewater injection wells, including key uncertainties. Some important facts and uncertainties include:

- While injection wells can operate for years without creating felt earthquakes, some wastewater injection wells have induced earthquakes that can cause structural damage and human injuries, and the number of documented cases is growing.
- While induced seismicity often occurs within months of injection, the onset can be delayed for many years — as much as 20 years in some instances — after the initiation of injection.⁵¹
- Induced seismicity, including large earthquakes, may continue for months to years after injection is stopped.

- While many induced earthquakes originate near the injection point, they have also occurred up to 7.5 miles (12 kilometers) away, indicating that the potential influence of wastewater injection wells can extend out many miles.⁵² Research has not established a maximum distance over which injection wells can induce earthquakes.
- The maximum possible magnitude of an induced earthquake that can be triggered by injection is unknown.

5. Hydraulic fracturing has induced felt earthquakes of magnitudes 2 and 3.

Fracking appears to pose a lower risk of inducing destructive earthquakes than the injection of oil and gas wastewater. Fracking intentionally cracks the shale rock around wells to release oil and gas deposits and routinely produces small earthquakes ($M < 1$) typically not felt at the surface.⁵³ However, several recent studies have reported that fracking has induced earthquakes of magnitudes 2 and 3 in Oklahoma, British Columbia, and the United Kingdom,⁵⁴ including a M3.8 event.

These cases illustrate that fracking can induce larger magnitude earthquakes when the rock formation being fracked intersects a fault:

Oklahoma: In January 2011, a series of 116 earthquakes, ranging from M0.6 to M2.9, occurred near a well being hydraulically fractured in south-central Oklahoma. Multiple earthquakes were felt by a local resident. A study by a scientist at the OGS found that the area was highly faulted, and concluded that “it is likely that hydraulic fracturing triggered the earthquakes observed in this study.”⁵⁵

British Columbia: A 2012 study by the British Columbia Oil and Gas Commission determined that seismic events reported in the Horn River Basin between April 2009 and December 2011 were caused when fracking fluids were injected into a fault.⁵⁶ A series of 38 earthquakes were recorded between M2.2 and M3.8, with the largest earthquake felt by workers.

United Kingdom: A series of earthquakes culminating in a M2.3 near Blackpool, England, in 2011 has been attributed to fracking.⁵⁷

6. Earthquakes may cause oil and gas leaks and spills, and pose a risk to groundwater near oil and gas infrastructure.

There is ample cause for concern about the potential harm to groundwater associated with earthquakes near oil and gas wells. All wells, including production and wastewater injection wells, rely on the integrity of the well casing to prevent contamination of underground aquifers. Seismic activity that occurs close to wells may increase the likelihood of damaging the well casing or cementing, which can allow contamination of underground sources of drinking and irrigation water from the migration of hydrocarbons, well stimulation and drilling chemicals, or produced water.

Well casing failures are common, but the extent to which they are caused by or exacerbated by seismic movement is unknown. In Pennsylvania, a study using data supplied by industry found failure rates of 6 to 9 percent.⁵⁸ A ProPublica review of injection wells nationwide found that from 2007 to 2010, more than 7,000 (3 percent) of 220,000 wells showed signs of leakage, and more than 17,000 (8 percent) had received violations.⁵⁹ The same report found that in California over that time period there were 12 cases of groundwater contamination and 63 cases of significant leaks from injection wells.⁶⁰

California lacks key data on well casing failures. DOGGR does not maintain a database of well casing failures, and the agency is unable to identify which wells have failed and the rate at which wells experience integrity failures. The unknown extent of well casing failures and the lack of understanding of the impacts of seismic activity on well casing integrity are especially troubling for California. The state's elevated risk of seismic activity, combined with additional induced seismicity risk from well stimulation and underground injection, could lead to disastrous consequences should an earthquake cause major well casing failures. The rate of well casing failure, along with the effects of seismic activity on well integrity, should be further analyzed to better understand the risk of groundwater contamination from oil and gas wells in California.

Although there is no comprehensive analysis, evidence of well casing failures linked to earthquakes already exists in the state. For example, in Ojai, California, API well #11101020 experienced a failure directly after an earthquake occurred on the nearby San Cayetano fault. According to DOGGR, on March 3, 2006, the Ojai 36 well, located in the Sespe oil field, 1.23 miles from the San Cayetano fault (Figure 2), was plugged and abandoned after a M3.1 earthquake triggered a 5 barrel-per-minute leak of produced water.⁶¹ The well log indicates that there is no record of when the well was initially drilled, but it was deepened in 1918. Like many existing oil and gas wells which were drilled decades ago, there is no record of any assessment of nearby faults and seismic threats to well casings.⁶²

In Ojai, California, API well #11101020 experienced a failure directly after an earthquake occurred on the nearby San Cayetano fault.

The example of Ojai 36 demonstrates how seismic events may cause well casing failure and that drilling in seismically active areas may pose increased risk of failures and potential groundwater contamination.

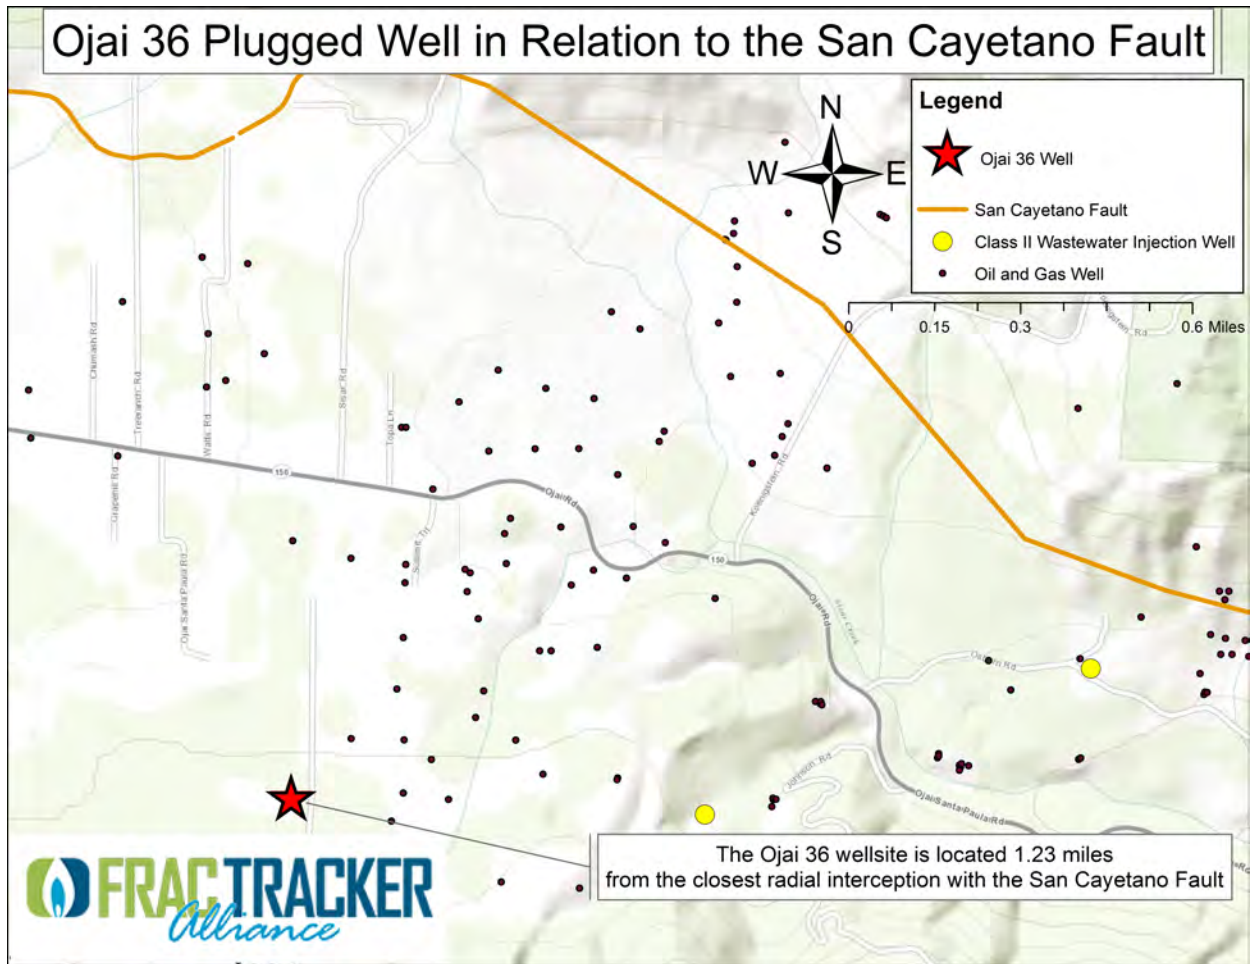

FIGURE 2: Location of Well Failure in Ojai, CA, In Relation to the San Cayetano Fault.

Evaluating Earthquake Risk from Wastewater Injection Wells and Fracking in California

1. California is one of the most seismically active states in the nation, with many active faults and more citizens and infrastructure at risk from earthquakes than any other state.

California lies within the planet's Ring of Fire, a seismically active region surrounding the Pacific Ocean from New Zealand, to Alaska, to Chile. Ninety percent of the world's earthquakes and 81 percent of the largest earthquakes occur along the Ring of Fire.⁶³ In California, there are thousands of small earthquakes per year that are attributed to the complex system of faults that crisscross the state. The most prominent is the San Andreas fault which cuts across California, forming the boundary between the Pacific and North American tectonic plates.⁶⁴ Other active faults are the San Jacinto fault in Southern California and the Mendocino Triple Junction in Northern California, which have historically produced large earthquakes.⁶⁵

Due to its frequent seismic activity and large population centers, California has more citizens and infrastructure at risk from earthquakes than any other U.S. state.⁶⁶ In fact, seven of the 10 U.S. metropolitan areas with the highest estimated annualized losses from earthquake damage are in California, with the Los Angeles-Long Beach-Santa Ana area ranking first.⁶⁷

The San Andreas fault and the Hayward-Rodgers Creek fault have the greatest probability of generating a large earthquake.⁶⁸ Many earthquakes typically occur within 31 miles (50 kilometers) of the San Andreas fault, including many with M7.0 or above. Examples include the 1906 San Francisco earthquake (M7.9) and the 1989 Loma Prieta earthquake (M7.0). A number of moderate to large earthquakes — M5.5 or above — have occurred in faults away from the San Andreas. These include the 1952 Kern County earthquake (M7.5), the 1971 San Fernando earthquake (M6.7), and the 1994 Northridge earthquake (M6.7).

In California, earthquakes pose added risks from landslides and liquefaction, particularly along the densely populated coast. Liquefaction, a type of ground failure specific to earthquakes, occurs when water-saturated sand and silt behave like a liquid due to the trembling of the earth. The soils can then no longer support structures, may flow down even gentle slopes, and erupt to the surface as sand boils. Liquefaction usually leads to settlement of the surface in uneven patterns that damage infrastructure such as buildings, roads, and pipelines.⁶⁹ Areas with high liquefaction hazards include

landfills, particularly those in areas once submerged by water, as well as wetlands, river floodplains, and stream channels.⁷⁰ Areas of particular concern for liquefaction include the margins of San Francisco Bay⁷¹ and parts of Los Angeles County (Figure 3).

FIGURE 3. Landslide and Liquefaction Zones in Southern CA with Class II Wastewater Injection Wells and Fracked Wells. Areas with high liquefaction hazards include landfills, particularly those in areas once submerged by water, as well as wetlands, river floodplains, and stream channels. Areas of particular concern for liquefaction include the margins of San Francisco Bay and parts of Los Angeles County.

2. More than half of California's 1,553 active wastewater injection wells are within 10 miles of a recently active fault.

Two interactive maps developed by the FracTracker Alliance show the current extent of oil and gas development, seismic activity, and seismic hazards throughout California. The maps depict the state's fault lines, wastewater injection wells, fracked and acidized wells, liquefaction and landslide hazard zones, and the Monterey Shale that is the focus for unconventional development. Users may zoom in and out to determine if their neighborhood is affected by oil and gas development and wastewater injection wells, or lies in a seismic hazard zone. Links are provided here: [California Geological Hazards Map](#), [Injection Wells and Hydraulic Fracturing in California's Fault Zones](#). In the maps, the fault history is categorized into four groups based on the last time that each fault was active: Historic (fault experienced earthquake activity in the last 150 to 200 years), Holocene (activity in the last 11,000 years), Late Quaternary (activity in the last 750,000 years), and Quaternary (activity in the last 1,600,000 years), using the definitions from the USGS and the California Geological Survey (CGS). Detailed descriptions of the maps are provided in Appendix A.

Based on this data, we analyzed the proximity of California's active and new Class II wastewater injection wells to faults in order to assess the risks that injection wells may pose to Californians. We evaluated recently active ("Historic") faults — defined as those with activity in the past 150 to 200 years — and Quaternary faults — defined as those with activity in the past 1.6 million years — using data from the CGS⁷² and USGS.⁷³ We also analyzed a subset of "high-magnitude faults" identified as causing earthquakes greater than M6. New wells are those that have been permitted, may have been drilled, but are not yet actively disposing fluids by injection. A detailed methodology is presented in Appendix A. The distances of both active and inactive wastewater injection wells to faults is presented in Appendix B.

Our analysis shows that more than half of California's 1,553 active and new Class II wastewater injection wells are within 10 miles of a recently active fault that has caused an earthquake in the past 200 years. Specifically, 834 wells (54 percent) are within 10 miles of a recently active fault, 350 wells (23 percent) are within 5 miles, and 87 wells (6 percent) are within 1 mile (Table 1). Of added concern, 42 wells are within 10 miles of a recently active, high-magnitude fault that has caused an earthquake greater than M6 in the past 150 years, 30 wells are within 5 miles, and one well is within 1 mile.

When all faults are considered, our analysis found that 1,197 active and new wastewater injection wells (77 percent) are within 10 miles of a Quaternary fault, 808 wells (52 percent) are within 5 miles, and 302 wells (19 percent) are within 1 mile (Table 2). Of these, 529 wells are within 10 miles of a high-magnitude Quaternary fault that has caused an earthquake greater than M6 in the past 1.6 million years, 249 wells are within 5 miles, and 53 wells are within 1 mile.

More than half of California's 1,553 active and new wastewater injection wells are within 10 miles of a recently active fault and almost one-quarter are within 5 miles.

The close proximity of California’s wastewater injection wells to faults raises significant cause for concern over the potential for these wells to induce earthquakes. Earthquakes have been induced at distances up to 7.5 miles (12 kilometers) from an injection well,⁷⁴ and many of California’s active wastewater injection wells are located much closer to faults. Scientists have recommended using 12.4 miles (20 kilometers) as the distance of concern for evaluating whether an injection well might induce an earthquake,⁷⁵ and the vast majority of California’s active and new injection wells lie within this distance.

| TABLE 1. Number of active and new wastewater injection wells within 1, 5, and 10 miles of recently active faults that have caused earthquakes in the past 200 years | |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| NUMBER OF ACTIVE/NEW WELLS (PERCENT) | DISTANCE TO FAULT |
| 87 wells (6%) | Within 1 mile |
| 350 wells (23%) | Within 5 miles |
| 834 wells (54%) | Within 10 miles |

| TABLE 2. Number of active and new wastewater injection wells within 1, 5, and 10 miles of Quaternary faults that have caused earthquakes in the past 1.6 million years | |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| NUMBER OF ACTIVE/NEW WELLS (PERCENT) | DISTANCE TO FAULT |
| 302 wells (19%) | Within 1 mile |
| 808 wells (52%) | Within 5 miles |
| 1,197 wells (77%) | Within 10 miles |

We also found that some of the state’s major population centers, such as Los Angeles and Bakersfield, are in regions where high densities of wastewater injection wells are located near recently active faults (Figure 4). The impacts of induced earthquakes can be particularly costly in these heavily populated regions.

Some of the state’s major population centers such as Los Angeles and Bakersfield are in regions where high densities of wastewater injection wells are near recently active faults.

FIGURE 4. California Faults with Class II Wastewater Injection Wells and Fracked Wells. High densities of wastewater injection wells are located near recently active faults.

We highlight three at-risk regions — Kern County, Ventura County, and Los Angeles County:

Kern County: Just to the west of Kern County lies the San Andreas fault — one of the most active faults in the world. Just a few miles from the fault, a large concentration of underground injection wells litters the landscape (Figure 5). There are additional injection wells throughout the county, as well as hundreds of oil wells that are actively fracked and acidized. In 1952, a M7.5 earthquake struck the city of Bakersfield, causing millions of dollars in damage. Kern County produces nearly 80 percent of all oil in California. An earthquake in the area could cause significant environmental damage from well ruptures and spills, as well as injuries, loss of life, and monetary damages.

FIGURE 5. Kern County Faults with Class II Wastewater Injection Wells and Fracked Wells

Ventura County: Wastewater injection and oil production, including fracking and acidizing, is occurring near faults in the mountains north of the cities of Ventura and Oxnard (Figure 6). These regions are also high-hazard areas for liquefaction and landslides. Should a significant earthquake occur, it would put hundreds of thousands of residents in danger and could cause billions of dollars in infrastructure damage. The CGS estimated a loss of nearly \$82 million in the Ventura-Oxnard area in 2010 due to seismic activity.⁷⁶ Ventura County lies in the southern edge of the Monterey Shale, one of the areas of most interest for future oil and gas development in the state.

FIGURE 6. Ventura County Faults with Class II Wastewater Injection Wells and Fracked Wells

Los Angeles County: One of the main areas of concern lies in Los Angeles County where underground injection wells and oil and gas wells subjected to hydraulic fracturing and acidizing are located very near faults that have been shown to be active in the past 150 to 200 years (Figure 7).

The Inglewood oil field, which lies just southwest of downtown Los Angeles and north of the Long Beach area, is littered with disposal wells that receive millions of gallons of wastewater every year. Estimates by the CGS showed a loss of nearly \$1.1 billion for the Long Beach/Los Angeles area from seismic activity in 2010 alone.⁷⁷

Were a major earthquake to occur, it could devastate the county. For example, the “ShakeOut Scenario” from the USGS and CGS estimated that a nearby M7.8 earthquake along the San Andreas fault could cause 1,800 fatalities and nearly \$213 billion in economic damages.⁷⁸ Additionally, much of Los Angeles County lies in high-hazard areas for liquefaction and landslides.

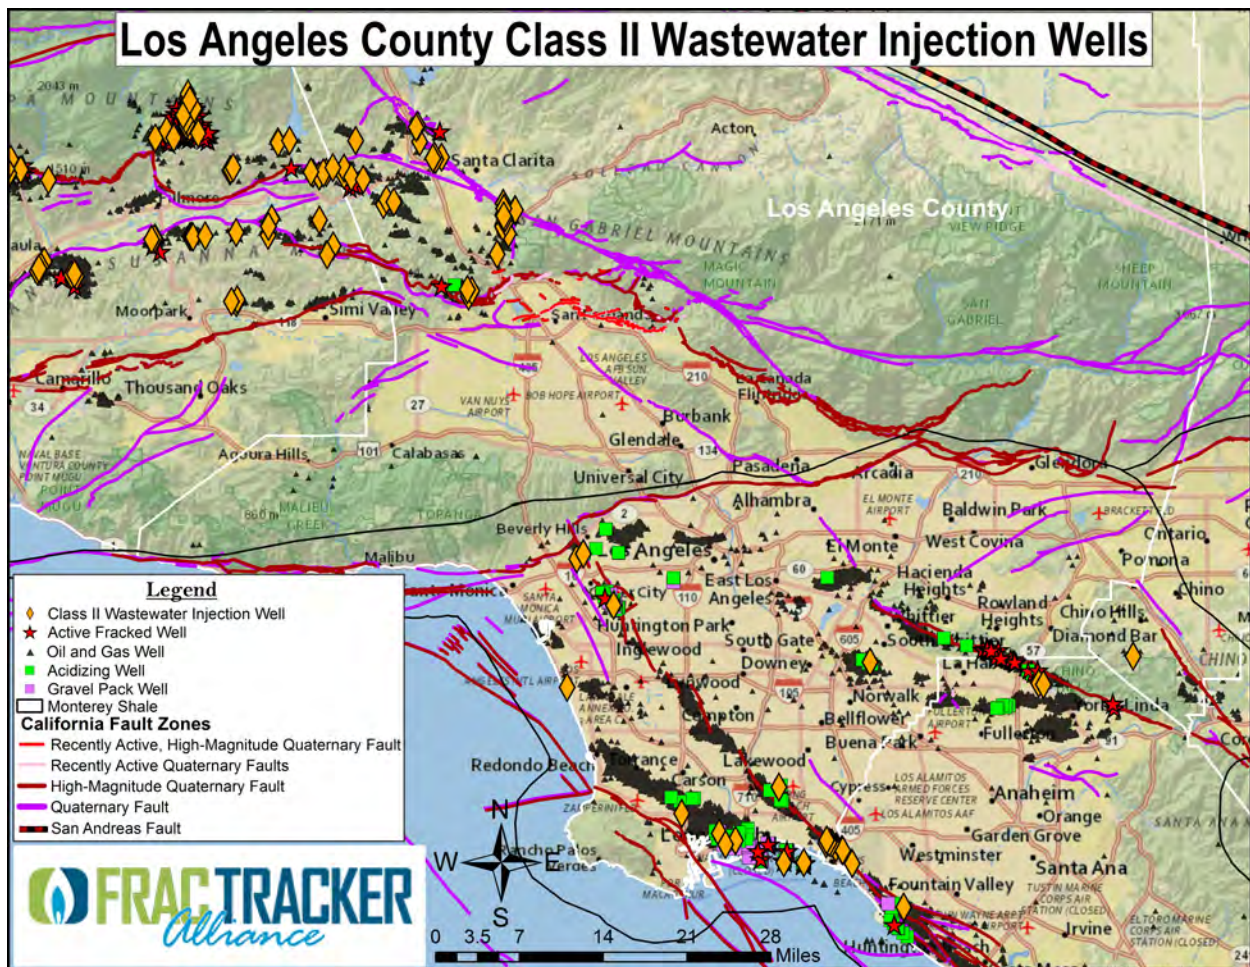

FIGURE 7. LA County Faults with Class II Wastewater Injection Wells and Fracked Wells

3. Critical gaps in monitoring and information prevent the effective detection and risk assessment of human-induced earthquakes.

Despite the advances in research linking wastewater injection wells to induced earthquakes in the Eastern and Midwestern U.S., very little research and monitoring of the earthquake risks from wastewater injection has been conducted in California, despite the state's long history with active faults. At present, no studies have evaluated the potential increase in earthquake risks from the several thousand existing wastewater injection wells, and fracked and acidized wells, in the state. In short, we simply do not know the extent to which existing oil and gas wells and wastewater injection wells in California may have already induced earthquakes.

Other fundamental questions related to the risks of induced seismicity from wastewater injection wells remain unanswered. Several key knowledge gaps exist:

- What is the largest earthquake that could be induced by wastewater injection and fracking activities?
- What is the maximum distance from a fault over which an injection well can induce an earthquake? Examples to date indicate that earthquakes have been induced up to 7.5 miles (12 kilometers) from an injection well.
- What is the time period following the initiation of injection over which earthquakes can be induced, since induced seismicity often occurs within months of initiation but can also occur after many years?
- How quickly can induced seismicity be "turned off" after stopping injection activities, since studies indicate that there may be delays of months or in some cases more than a year?
- How does the density of wells in an area affect the risk of inducing an earthquake? Does a greater density of wells increase this risk?
- What is the risk that wastewater injection wells and oil and gas production wells (including those that have been stimulated), including plugged and abandoned wells, could be damaged by earthquake activity so that they contaminate drinking water sources?
- When and why will a particular injection well induce an earthquake? Why do some injection wells induce earthquakes while others in the same region do not?

Unfortunately, much of the information needed to assess earthquake risks from wastewater injection and oil and gas production wells in California is lacking or incomplete because of (1) the state's failure to require the oil and gas industry to submit critical fluid injection data, (2) gaps in the state's earthquake monitoring networks, and (3) the limitations on collecting comprehensive information on faults and geology.

California regulations have two primary requirements related to fluid injection data from wastewater injection wells: (1) the permit for an injection well must include an injection plan with an estimate of the maximum-anticipated surface injection pressure and daily rate of injection, and an analysis of the injection liquid,⁷⁹ and (2) “data shall be maintained to show performance of the project and to establish that no damage to life, health, property, or natural resources is occurring by reason of the project.”⁸⁰ At present, California only requires industry to submit coarse-scale monthly injection volumes and wellhead pressures,⁸¹ which makes it difficult to determine whether a particular wastewater injection well may have induced an earthquake.

The quantity and distribution of seismic monitoring stations are critical for accurately characterizing the seismicity of a region and determining whether an earthquake is natural or induced. In California, monitoring and reporting of earthquake activity is coordinated under the California Integrated Seismic Network (CISN), a public and private network of monitoring stations.⁸²

According to the CISN, the number, type, and distribution of seismic stations are sparse in many parts of the state, and considered inadequate for “producing the best quality of earthquake information from all parts of the state.”⁸³ Collecting data on smaller magnitude earthquakes between magnitudes 1.5 and 2 is particularly important since these smaller earthquakes are much more common than larger ones, can provide warnings that larger magnitude earthquakes are coming, and allow for the statistically robust detection of induced earthquakes.

Critical information on faults and geology is also lacking. California’s fault maps are not complete. Some potentially destructive fault types, such as strike-slip faults and blind thrust faults, can be difficult to detect even with traditional seismic imaging technology.⁸⁴ Modern 3-D seismic imaging technology that allows for better fault detection is very costly, making it unlikely to be commonly used. There are technological limitations on collecting information on the geological characteristics related to induced seismicity, including pore pressure, permeability, existing stresses, and hydrological connectivity to deeper faults.

4. California regulations do not address the risks of induced earthquakes from wastewater injection wells or fracking.

Underground injection wells for oil and gas wastewater are regulated by the federal Safe Drinking Water Act’s Underground Injection Control Program (UIC) and are classified as Class II wells. The EPA granted the State of California primacy to implement the UIC Class II program in California in 1982.⁸⁵ The federal UIC Class II regulations and California’s UIC Class II program do not adequately address the risks of induced seismicity from wastewater injection wells.

Neither EPA’s federal regulations for Class II wells nor California’s UIC Class II program contain provisions specific to seismicity, and neither require operators to collect and submit the information needed to assess the risks of induced seismicity. Class II provisions can be compared to the UIC Class I program, which covers hazardous and non-hazardous waste from industrial and municipal sources.⁸⁶ Because

wastewater from oil and gas production was exempted from hazardous waste regulations under the Resource Conservation and Recovery Act (RCRA), it is not classified as “hazardous” regardless of its composition and is not required to be disposed of under the more stringent requirements of the UIC Class I program.⁸⁷

UIC Class I regulations include requirements for minimizing earthquake risk during well siting, including studies to demonstrate that the injection area has low background seismicity and that the proposed injection will not induce earthquakes.⁸⁸ Rules for Class I wells require geologic analysis of a much larger area surrounding each well to demonstrate that hazardous materials will not move out of the injection zone. They also mandate more stringent protocols for construction, operation, testing, and monitoring, as well as monitoring of the well and groundwater after the well is plugged. The weaker regulations for Class II wastewater injection wells may increase the risks of inducing earthquakes and contaminating drinking water.

Current DOGGR regulations for Class II wastewater injection wells are inadequate for protecting against the risks of induced earthquakes. The regulations related to earthquake risks only require that applications for injection projects include a map showing “reservoir characteristics such as... faults,”⁸⁹ without providing guidance on how to evaluate faults. Moreover, DOGGR only requires the industry to submit coarse-scale, monthly fluid injection volume and wellhead pressure data,⁹⁰ which makes it difficult to determine whether a particular wastewater injection well may have induced an earthquake.⁹¹

Notably, DOGGR does not require any seismic monitoring at or near wastewater injection wells, nor does it conduct any macro-level analysis — for multiple injection projects or on the field level — of the potential seismic impacts based on the planned or reported injection data.⁹² All analysis of these data is on a project only level, which does not address any changes in seismic risk due to high concentrations of disposal well projects within a given field or area, or how neighboring injection projects interact on a cumulative level with surrounding faults.

In sum, although the regulations state that DOGGR should maintain data “to establish that no damage to life, health, property, or natural resources is occurring by reason of the project,”⁹³ DOGGR does not require the collection and assessment of the geological or fluid injection data needed to adequately evaluate the risks from induced earthquakes, or detect whether induced earthquakes are occurring.

Additionally, in July 2011, Environmental Protection Agency’s Region 9 found DOGGR’s implementation of its Class II program inadequate in several regards.⁹⁴ Specifically, the critique highlights DOGGR’s one-size-fits-all Area of Review (AOR) standard that only requires review of a quarter-mile radius around the well, which could result in insufficient analysis of surrounding geologic features such as faults.⁹⁵ DOGGR has no systematic process for assessing geologic features outside of the quarter-mile AOR.⁹⁶ It appears that this process is ad-hoc and not adequate for identifying important geologic features outside of the quarter-mile radius AOR, and the potential for induced seismic events on faults more than a quarter-mile away from a disposal well. Due to the urgency of the

identified deficiencies, the EPA requested that DOGGR provide an “action plan” to address them no later than September 1, 2011.⁹⁷ Despite the passage of more than two years, DOGGR has to date failed to bring its program into compliance with federal requirements.

DOGGR’s November 2013 proposed regulations for well stimulation touch briefly on earthquake risks associated with well stimulation activities, but do not require any seismic monitoring to detect induced seismicity and mandate no action to respond to or potentially mitigate human-induced earthquakes.⁹⁸ The proposed regulations require the following:

- that evaluation prior to well stimulation include a review of all faults within a radius of twice the anticipated well-stimulation treatment length (Section 1784), and
- that the report submitted within 60 days of ending a well stimulation treatment will note if “data from the USGS indicates that, since the commencement of a well stimulation treatment, any earthquake of M2.0 or greater has occurred in the area of the well stimulation treatment radius” (Section 1789).⁹⁹

In 2012, the National Academy of Sciences (NAS) recommended that states and regulators should take steps to prevent human-induced earthquakes.¹⁰⁰ The NAS panel was chaired by Colorado School of Mines professor Murray Hitzman, who cautioned that earthquakes associated with drilling can pose a risk to public health and safety.¹⁰¹

California oil and gas regulators have ignored these recommendations. State officials have said they don’t need to look at injection wells and earthquakes, stating that the current rules are sufficient. In 2012, DOGGR spokesman Don Drysdale stated: “While seismicity is not specifically mentioned in the California Code of Regulations, DOGGR believes it is adequately addressed. Operators must evaluate oil and gas reservoirs prior to injection, and that evaluation includes faulting.”¹⁰² Not only has DOGGR failed to provide guidance or regulation that makes clear to the regulated community how to evaluate “faulting,” the agency does not appear to have given much consideration to the risks associated with induced seismicity related to wastewater injection in California, or the risks of well-casing failure in areas that are notable for significant seismic activity.

5. The best way to protect Californians is to halt hydraulic fracturing, acidizing, and other unconventional oil and gas recovery techniques.

Fracking and other unconventional oil and gas extraction techniques are accompanied by numerous risks, including climate disruption, air and water pollution, public health impacts, the use of scarce water resources, and the production of billions of gallons of contaminated wastewater. New and ongoing research has established that much of the increased earthquake activity, and many of the large earthquakes in the Eastern and Midwestern U.S. where fracking-enabled oil and gas production has boomed, can be attributed to the underground injection of wastewater, providing yet more

evidence of the negative consequences of fracking, acidizing, and other unconventional extraction techniques.

Our analysis of wastewater injection wells and faults in California found that 87 wastewater injection wells are within 1 mile of a recently active fault, 350 wells are within 5 miles, and 834 wells are within 10 miles. The proximity between many existing wastewater injection wells and recently active faults raises significant cause for concern over the potential for these wells to induce earthquakes.

In California, inadequate monitoring and research, fundamental knowledge gaps, and poor regulation indicate that Californians are not being protected from the earthquake risks posed by wastewater injection wells and fracking. Yet the state may be on the verge of rapid expansion of fracking and other techniques that will dramatically increase the use of wastewater injection wells.

California's current regulations do not adequately address the risks of induced earthquakes from wastewater injection wells and fracking. Additionally, California's proposed well stimulation regulations do almost nothing to reduce the risk of induced seismicity. The proposed DOGGR rules on well stimulation do not mandate the collection and assessment of data to proactively evaluate seismic risk during siting of wells, nor do they require seismic monitoring before, during, or after well operation or actions to respond to and mitigate potential induced-earthquake activity.

Induced earthquakes can impose large safety and economic costs on the public. Earthquakes induced by wastewater injection and fracking can affect a broad area beyond the well, causing damage to homes, workplaces, infrastructure, and potentially cause injury or devastating loss of human life. The public can also pay a high economic price. In response to the earthquake swarms occurring in Oklahoma, the state insurance commissioner recommended that Oklahomans buy earthquake insurance, which comes with prohibitive out-of-pocket costs to repair earthquake damage due to high deductibles,¹⁰³ as well as skyrocketing insurance rates near earthquake epicenters.¹⁰⁴

Through inaction and failure to address the potential risks, the state has in effect transferred to the public many of the potential risks and costs associated with induced seismicity, well-casing failure, and associated leaks that might be caused by earthquakes. Without effective monitoring or regulatory systems in place, those harmed by property damage, water contamination, or other harm will likely face daunting challenges to demonstrating that oil and gas operations caused the harm. By failing to require adequate monitoring and through lack of oversight, California's Department of Conservation fails to comply with its legal mandate to protect public safety and welfare. Furthermore, the state enables companies that profit from oil and gas production to transfer the risks associated with seismicity to the public.

It has been suggested that earthquake risks from wastewater injection wells can be managed if the industry follows a strict series of steps for study and planning prior to injection, performs monitoring in areas where seismicity might be triggered, and establishes protocols for responding, including potential well abandonment if induced seismicity occurs.¹⁰⁵ Existing and proposed California regulations do not require oil and gas operators to take any of these steps. Instituting this system would require far-reaching changes to business-as-usual practices that work in the industry's favor.

Implementing the best-possible system to monitor and manage earthquake risks from wastewater injection wells and fracking could reduce — but not eliminate — the risks to Californians. There are significant technological and cost limitations for locating faults and characterizing geology, as well as large knowledge gaps, which limit the ability to effectively address the risks. Moreover, even the best monitoring and management system would still place safety and economic burdens on the public. Due to these limitations, DOGGR cannot safely regulate induced seismicity.

In light of the known environmental and health risks from unconventional extraction and wastewater disposal, the link between wastewater injection wells and earthquakes in other states, the potential for a huge expansion of drilling and wastewater production in the Monterey Shale, and the gaps in scientific knowledge regarding induced seismicity, the best way to protect Californians is to halt hydraulic fracturing, acidizing, and other unconventional oil and gas recovery techniques. Moreover, no oil and gas wastewater disposal should be allowed that does not account for all risks, including seismic risks.

We would like to thank our supporters for their generosity. We would like to thank the FracTracker Alliance for developing the [California Geological Hazards Map](#), and the [Injection Wells and Hydraulic Fracturing in California's Fault Zones](#) maps. We also thank Curt Bradley (Center for Biological Diversity) for assistance with the GIS analyses.

Appendix A: Research and Methodology

The data used to generate the “[California Geological Hazards](#)” and “[Injection Wells and Hydraulic Fracturing in California's Fault Zones](#)” maps on FracMapper come from several sources, including DOGGR, CGS, and USGS. Several map layers were downloaded as shapefiles and imported directly into ArcGIS without amendments, while other datasets were aggregated, queried or significantly edited to produce the map layers.

The well-site locations were downloaded as the full DOGGR dataset, available as “[AllWells.zip](#).” The DOGGR database was queried to separate the individual well-types into the various map layers, and differentiate between new, active, idle, plugged, and buried wells. “New” wells have been permitted, but have not yet been drilled. The permit is valid for one year, or up to two years upon request. The database includes an identifier for hydraulically fractured wells; these wells were isolated and then combined with the [SkyTruth.org](#) database of hydraulically fractured wells, which they extract from [FracFocus.org](#). The hybrid dataset can be downloaded from FracTracker ([CA Hydraulically Fractured Wells](#)). An additional well-site database showing well sites within the South Coast Air Quality Monitoring District is also projected in the maps. The California high-magnitude quaternary faults map layer was generated by clipping the USGS [dataset](#) for the entire United States. The dataset of “Named California Faults” also used for the proximity analysis was retrieved from CGS. The [Hayward fault](#)

shapefile was downloaded from USGS as a package also containing landslide hazard zones. The “Named Faults” dataset that was used for part of the proximity analysis was produced by eliminating all unnamed quaternary fault-lines from the [CGS fault database](#).

The statewide shaking hazards map layers estimate the amplification based on the underlying geology of the soil. A research group consisting of both USGS and CGS geologists developed [risk hazards available as shapefiles](#) for both high frequency and low frequency seismic events. High frequency shaking poses a hazard for short building structures, while low frequency shaking is the most hazardous to large multi-story cityscape buildings. For the Bay Area and East Bay, additional shaking hazards analyses have been completed. Liquefaction risks have been estimated by USGS and CGS specifically for the [Bay Area](#), Alameda County and multiple fault-slip scenarios for [Santa Clara](#) in separate assessments. All shapefiles are viewable individually in the [California Geological Hazards Map](#).

There are no regional liquefaction risk estimate maps available outside of the Bay Area, although the CGS has identified regions of liquefaction and landslide hazards zones for the metropolitan areas surrounding the Bay Area and Los Angeles. These maps outline the areas where liquefaction and landslides can be expected given a standard set of conservative assumptions. These [datasets](#) are only available via individual 7.5-minute quadrangles. To produce the map layers FracTracker aggregated the quadrangles, and combined the data into unified datasets, downloadable here; [Landslide and Liquefaction](#).

For the proximity analysis of Class II wastewater injection wells and faults, we used the most recently updated dataset from DOGGR, posted [9/27/13](#), which identified 2,583 total Class II water injection wells. Of those, 2,578 entries had latitude/longitude data, with 1,473 wells listed as “active,” 80 listed as “new,” and 1,031 listed as “plugged.” The proximity analysis included the 1,553 wells listed as “active” or “new.” We used the North American Datum 1983 State Plane California IV FIPS 0404 projection because the majority of Class II Water Disposal wells are located in Kern County. The analysis was conducted using ESRI’s ArcGIS ArcMap V. 10.1 software. We used two fault databases: (1) the California Geological Survey 2010 Fault Activity Map of California, and (2) the U.S. Geological Survey Quaternary Fault and Fold Database of the U.S. Buffers were created around the Class II Injection Well shapefiles, and the ‘intersect’ function was used to generate the proximity datasets. Database management was conducted using IBM SPSS Statistics v.20 software.

Appendix B: Analysis of the Distances of All (Active, New, Idle, Plugged, and Buried) Class II Injection Wells to Faults

This Appendix presents analyses similar to those presented for active and new Class II wastewater injection wells, but includes both active and inactive wastewater injection wells, including active, new, idle, plugged, and buried wells, totaling 2,578 wells with location data.

Our analysis shows that 1,177 (46 percent) of California’s 2,578 active and inactive wastewater injection wells are within 10 miles of a recently active fault that has caused an earthquake in the past 200 years, 527 wells (20 percent) are within 5 miles, and 112 wells (4 percent) are within 1 mile (Table 1). Of added concern, 115 wells are within 10 miles of a recently active, high-magnitude fault that has

caused an earthquake greater than M6 in the past 150 years, 94 wells are within 5 miles, and 3 wells are within 1 mile.

When all faults are considered, our analysis found that 1,936 active and inactive wastewater injection wells (75 percent) are within 10 miles of a Quaternary fault, 1,422 wells (55 percent) are within 5 miles, and 527 wells (20 percent) are within 1 mile (Table 2). Of these, 1,001 wells are within 10 miles of a high-magnitude Quaternary fault that has caused an earthquake greater than M6 in the past 1.6 million years, 606 wells are within 5 miles, and 135 wells are within 1 mile.

| TABLE 1. Number of active and inactive wastewater injection wells within 1, 5, and 10 miles of recently active faults that have caused earthquakes in the past 200 years | |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| NUMBER OF WELLS (PERCENT) | DISTANCE TO FAULT |
| 112 (4%) | Within 1 mile |
| 527 (20%) | Within 5 miles |
| 1,177 (46%) | Within 10 miles |

| TABLE 2. Number of active and inactive wastewater injection wells within 1, 5, and 10 miles of Quaternary faults that have caused earthquakes in the past 1.6 million years | |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| NUMBER OF WELLS | DISTANCE TO FAULT |
| 527 (20%) | Within 1 mile |
| 1,422 (55%) | Within 5 miles |
| 1,936 (75%) | Within 10 miles |

- According to the U.S. EPA website (<http://water.epa.gov/type/groundwater/uic/class2/>) there are approximately 144,000 Class II wells in operation in the US, injecting over 2 billion gallons of wastewater everyday. Most of these are located in Texas, California, Oklahoma, and Kansas. Three types of Class II wells are associated with the industry: 1) Enhanced recovery wells – flowback fluids, along with other liquids and gases are injected to recover residual oil and gas. This is known as secondary or tertiary recovery. These are the most common type, accounting for nearly 80% of all Class II wells. 2) Disposal wells – flowback fluids are injected into the same, or similar, formations as the well from which it was extracted. Disposal wells account for approximately 20% of all Class II wells. 3) Hydrocarbon storage wells – these serve as underground storage for hydrocarbons, and are found in formations (such as salt caverns). The main use of these wells is for the US Strategic Petroleum Reserve. There are over 100 hydrocarbon storage wells in operation.

Re: 2040 General Plan Environmental Impact Report (EIR)

Dear Mr. Hedrick and Honorable Members of APAC:

Thank you for the opportunity to provide comments following today's presentation by Ventura County Planning staff on the 2040 General Plan EIR.

There are several issues with the 2040 General Plan EIR that CoLAB believes will negatively impact the viability of local agriculture.

Proposed mitigation measure AG-2: The County proposes that any project that either directly or indirectly results in the loss of farmland must obtain and place into perpetual agricultural preservation twice the total of the farmland loss. This mitigation measure is infeasible. Contrary to statements made by County Planning staff today at the APAC meeting, the California Environmental Quality Act (CEQA) requires that all mitigation proposed in an EIR be feasible. CEQA Section 21061.1 defines feasible as “capable of being accomplished in a successful manner within a reasonable period of time,

” (*emphasis added*). All mitigation measures proposed in an EIR must be shown to reduce impacts

and an infeasible mitigation measure, by definition, cannot and will not reduce impacts.

The EIR does not provide evidence of any of the following:

1. 1) Whether there is sufficient land available for purchase/conservation easement for each farmland category;
2. 2) The cost per acre to purchase each category of farmland;
3. 3) The anticipated cost of establishing a conservation easement for each category of farmland;
4. 4) The anticipated cost associated with managing each category of farmland under a conservation easement;
5. 5) The anticipated cost associated with monitoring these mitigation parcels scattered throughout the County and who will bear that cost;
6. 6) Any information that could constitute a “plan” for management of farmland in conservation easements;

February 19, 2020

Ventura County Coalition of Labor, Agriculture and Business / 1672 Donlon Street, Ventura, CA 93003 / 805-633-2260 / info@colabvc.org

Page 2 of 4

7. 7) An analysis of direct and indirect impacts caused by this mitigation measure (including impacts associated with LU compatibility conflicts and increased urban-ag-interface);
8. 8) Whether the smallest possible mitigation acreage required will achieve the minimum to ensure viability of agriculture on the parcel; and
9. 9) Whether the proposed mitigation is in conflict with other ordinances and regulations, such as the County's Zoning Ordinance and the County's minimum lot sizes.

The County is already aware that this proposed mitigation measure is infeasible. On March 24, 2016, at a Local Agency Formation Commission (LAFCo) hearing, Supervisor Linda Parks attempted to establish an "Agricultural Mitigation Measure" through the LAFCo project approval process. The mitigation measure would have required the 1-to-1 purchase of local farmland (half of what is proposed in the 2040 General Plan EIR) to replace farmland that would be impacted by any proposed development. Ventura County Counsel, Michael Walker, informed both LAFCo and Supervisor Parks that the proposed mitigation measure did not meet the standard for economic feasibility, and, for that and other reasons, LAFCo could not adopt Supervisor Park's proposed mitigation measure. He referenced a 2015 legal decision, *City of Irvine v. County of Orange*, in which the Court stated, "the sheer astronomical expense of land supports the finding of the EIR that the purchase of an agricultural conservation easement is a non-starter."

In addition to being infeasible, CoLAB does not believe that this mitigation measure will reduce impacts on agricultural land, as it does not address the actual issues that will impact farmland under the 2040 General Plan: lack of economic sustainability, the increasing regulatory demands on agriculture, increased competition for water resources, and increased compatibility conflicts from development.

Indirect Impacts

The EIR dismisses "indirect impacts" that will occur as a result of implementing the 2040 General Plan as "less than significant."

Page 4.2-13 of the EIR states "AG-2.3 maintains the Right-to-Farm Ordinance to protect agricultural land uses from conflicts with non-agricultural uses, as well as to help land purchasers and residents understand the potential for nuisance, (e.g., dust, noise, odors) that may occur as the natural result of living in or near agricultural areas...These sections of the code protect farmers engaged in agricultural activity from public nuisance claims...This protects the farming community, including Important Farmlands and farms less than 10 acres, from developments that would inhibit their ability to continue agricultural production."

Page 4.2-17 of the EIR states: "Residential growth in areas nearby agricultural lands has the potential to result in land use conflicts. Residential land uses are generally more sensitive and prone to conflict with adjacent agricultural land uses than commercial or industrial land uses. The placement of sensitive land uses, such as residences and schools, nearby classified farmland can negatively impact both uses due to conflict including odor nuisances and noise from agriculture machinery. The countywide Right-to-Farm Ordinance protects existing agricultural and farming operations from conflicts attributed to residential development...Therefore, the potential for conflicts would be minimal. This impact would be less than significant" (*emphasis added*).

This is simply not true. Historic and recent County actions have shown that the County has and will continue to create new restrictions and ordinances that have a significant impact on existing agricultural

Ventura County Coalition of Labor, Agriculture and Business / 1672 Donlon Street, Ventura, CA 93003 / 805-633-2260 / info@colabvc.org

Page 3 of 4

and farming operations because of conflicts attributed to residential development. The recent interim

urgency ordinance restricting hemp cultivation is one such example.

Contrary to statements made today by Ventura County Planning staff, an EIR, whether it is labeled as “programmatic” or “project”, must analyze all reasonably foreseeable consequences of the action that is proposed. For the 2040 General Plan EIR, the action proposed is the implementation of all policies and programs within. Therefore, if the implementation of a policy in the 2040 General Plan will result in an impact, that impact must be analyzed. For example, the 2040 General Plan contains land use designation changes that will increase allowable housing density near agricultural land. It is reasonably foreseeable that more houses will create more compatibility conflicts with normal farming operations. The impact of these compatibility conflicts must be addressed in the EIR.

In 2014, the California Court of Appeal stated in a ruling that “[T]he fact that this EIR is labeled a ‘project’ rather than a ‘program’ EIR matters little....Designating an EIR as a program EIR ... does not by itself decrease the level of analysis otherwise required in the EIR. All EIRs must cover the same general content. The level of specificity of an EIR is determined by the nature of the project and the “rule of reason,” rather than any semantic label accorded to the EIR.”

It is CoLAB’s opinion that indirect impacts from increasing urban-ag interface are SIGNIFICANT and cannot be dismissed in the EIR.

Direct and indirect impacts of increased costs

The 2040 General Plan has policies that will increase the costs of normal farming operations. CoLAB believes that the most effective way to minimize conversion of agricultural land to non-agricultural uses is to take active measures to allow farming to remain profitable. And even the County admits that reducing the cost of farming reduces conversion of agricultural land in their discussion of the Williamson Act in Chapter 4.2 of the EIR.

But the County fails to analyze direct and indirect impacts of 2040 General Plan policies that will increase the cost of normal farming operations, such as:

- Policy AG-5.2: Electric- or Renewable-Powered Agricultural Equipment. The County shall encourage and support the transition to electric- or renewable-powered or lower emission agricultural equipment in place of fossil fuel-powered equipment when feasible.

- Policy AG-5.3: Electric- or Renewable-Powered Irrigation Pumps. The County shall encourage farmers to convert fossil fuel-powered irrigation pumps to systems powered by electric or renewable energy sources, such as solar power, and encourage electric utilities to eliminate or reduce standby charges.

Direct and indirect impacts of increased competition for water resources
 The County fails to evaluate the impact of increased competition for water resources caused by development allowed in the 2040 General Plan on either the conversion of agricultural land or the loss of agricultural lands through the loss of topsoil.

The EIR states on page 4.2-3 that "...a reduction in available water resources for irrigation" is an example of indirect impacts on agricultural land due to loss of topsoil from increased wind and water erosion.
 But the County fails to analyze or propose mitigation measures to address this significant impact.

Ventura County Coalition of Labor, Agriculture and Business / 1672 Donlon Street, Ventura, CA 93003 / 805-633-2260 / info@colabvc.org

Page 4 of 4

APAC is the expert charged with advising County decision-makers on agricultural issues in Ventura County. And the County should be seeking guidance from APAC about the actual issues that will impact farmland under the 2040 General Plan: lack of economic sustainability, the increasing regulatory demands on agriculture, increased competition for water resources, and increased compatibility conflicts from development.

CoLAB encourages APAC to provide guidance to the County on appropriate and effective mitigation measures to prevent the conversion of agricultural land to non-agricultural uses. These may include:

- 1) Strengthen the Right-to-Farm ordinance to prevent nuisance complaints from being used to justify the creation or expansion of setbacks or regulatory restrictions on normal farming practices;
- 2) Expand the Land Conservation Act Program to include Open Space zoned properties that are engaged in farming (including grazing); and
- 3) Protect agricultural land from urban-ag interface encroachment and compatibility conflicts by establishing setbacks on NON-AE-zoned land that will restrict the construction of bike paths, public trails, and sensitive receptors within 2000' of any land zoned A/E.

Thank you again for the opportunity to provide comments on this issue. We appreciate your consideration and leadership at this time.

Sincerely,

Louise Lampara Executive Director

Page 2 of 4

7. 7) An analysis of direct and indirect impacts caused by this mitigation measure (including impacts associated with LU compatibility conflicts and increased urban-ag-interface);
8. 8) Whether the smallest possible mitigation acreage required will achieve the minimum to ensure viability of agriculture on the parcel; and
9. 9) Whether the proposed mitigation is in conflict with other ordinances and regulations, such as the County’s Zoning Ordinance and the County’s minimum lot sizes.

The County is already aware that this proposed mitigation measure is infeasible. On March 24, 2016, at a Local Agency Formation Commission (LAFCo) hearing, Supervisor Linda Parks attempted to establish an “Agricultural Mitigation Measure” through the LAFCo project approval process. The mitigation measure would have required the 1-to-1 purchase of local farmland (half of what is proposed in the 2040 General Plan EIR) to replace farmland that would be impacted by any proposed development. Ventura County Counsel, Michael Walker, informed both LAFCo and Supervisor

Parks that the proposed mitigation measure did not meet the standard for economic feasibility, and, for that and other reasons, LAFCo could not adopt Supervisor Park's proposed mitigation measure. He referenced a 2015 legal decision, *City of Irvine v. County of Orange*, in which the Court stated, "the sheer astronomical expense of land supports the finding of the EIR that the purchase of an agricultural conservation easement is a non-starter."

In addition to being infeasible, CoLAB does not believe that this mitigation measure will reduce impacts on agricultural land, as it does not address the actual issues that will impact farmland under the 2040 General Plan: lack of economic sustainability, the increasing regulatory demands on agriculture, increased competition for water resources, and increased compatibility conflicts from development.

Indirect Impacts

The EIR dismisses "indirect impacts" that will occur as a result of implementing the 2040 General Plan as "less than significant."

Page 4.2-13 of the EIR states "AG-2.3 maintains the Right-to-Farm Ordinance to protect agricultural land uses from conflicts with non-agricultural uses, as well as to help land purchasers and residents understand the potential for nuisance, (e.g., dust, noise, odors) that may occur as the natural result of living in or near agricultural areas...These sections of the code protect farmers engaged in agricultural activity from public nuisance claims...This protects the farming community, including Important Farmlands and farms less than 10 acres, from developments that would inhibit their ability to continue agricultural production."

Page 4.2-17 of the EIR states: "Residential growth in areas nearby agricultural lands has the potential to result in land use conflicts. Residential land uses are generally more sensitive and prone to conflict with adjacent agricultural land uses than commercial or industrial land uses. The placement of sensitive land uses, such as residences and schools, nearby classified farmland can negatively impact both uses due to conflict including odor nuisances and noise from agriculture machinery. The countywide Right-to-Farm Ordinance protects existing agricultural and farming operations from conflicts attributed to residential development...Therefore, the potential for conflicts would be minimal. This impact would be less than significant" (*emphasis added*).

This is simply not true. Historic and recent County actions have shown that the County has and will continue to create new restrictions and ordinances that have a significant impact on existing agricultural

and farming operations because of conflicts attributed to residential development. The recent interim

urgency ordinance restricting hemp cultivation is one such example.

Contrary to statements made today by Ventura County Planning staff, an EIR, whether it is labeled as "programmatic" or "project", must analyze all reasonably foreseeable consequences of the action that is proposed. For the 2040 General Plan EIR, the action proposed is the implementation of all policies and programs within. Therefore, if the implementation of a policy in the 2040 General Plan will result in an impact, that impact must be analyzed. For example, the 2040 General Plan contains land use designation changes that will increase allowable housing density near agricultural land. It is reasonably foreseeable that more houses will create more compatibility conflicts with normal farming operations. The impact of these compatibility conflicts must be addressed in the EIR.

In 2014, the California Court of Appeal stated in a ruling that "[T]he fact that this EIR is labeled a 'project' rather than a 'program' EIR matters little....Designating an EIR as a program EIR ... does not by itself decrease the level of analysis

otherwise required in the EIR. All EIRs must cover the same general content. The level of specificity of an EIR is determined by the nature of the project and the “rule of reason,” rather than any semantic label accorded to the EIR.”

It is CoLAB’s opinion that indirect impacts from increasing urban-ag interface are SIGNIFICANT and cannot be dismissed in the EIR.

Direct and indirect impacts of increased costs

The 2040 General Plan has policies that will increase the costs of normal farming operations. CoLAB believes that the most effective way to minimize conversion of agricultural land to non-agricultural uses is to take active measures to allow farming to remain profitable. And even the County admits that reducing the cost of farming reduces conversion of agricultural land in their discussion of the Williamson Act in Chapter 4.2 of the EIR.

But the County fails to analyze direct and indirect impacts of 2040 General Plan policies that will increase the cost of normal farming operations, such as:

- Policy AG-5.2: Electric- or Renewable-Powered Agricultural Equipment. The County shall encourage and support the transition to electric- or renewable-powered or lower emission agricultural equipment in place of fossil fuel-powered equipment when feasible.
- Policy AG-5.3: Electric- or Renewable-Powered Irrigation Pumps. The County shall encourage farmers to convert fossil fuel-powered irrigation pumps to systems powered by electric or renewable energy sources, such as solar power, and encourage electric utilities to eliminate or reduce standby charges.

Direct and indirect impacts of increased competition for water resources

The County fails to evaluate the impact of increased competition for water resources caused by development allowed in the 2040 General Plan on either the conversion of agricultural land or the loss of agricultural lands through the loss of topsoil.

The EIR states on page 4.2-3 that “...a reduction in available water resources for irrigation” is an example of indirect impacts on agricultural land due to loss of topsoil from increased wind and water erosion.

But the County fails to analyze or propose mitigation measures to address this significant impact.

To: Susan Curtis-

County failed to evaluate mitigation measures for feasibility- 500' set back for "sensitive receptors" from freeways and high traffic roads.

Mitigation Measure AQ-3 (Policy HAZ10-X) creates a minimum 500' set back for "sensitive receptors" from freeways and high traffic roads. Yet the County states in the Land Use section of the EIR that "the majority of the anticipated build-out will be within the freeway corridors."

Has the County completed a "buildout study" to ensure that the establishment of this set back still leaves enough room for development to occur? Will this mitigation measure be economically feasible?

February 27, 2020

Dear Susan Curtis,

Our comments are about the Draft Environmental Impact Analysis of the Agriculture Element of the VC2040 General Plan. We have serious concerns about other chapters, especially Water Resources, but time does not permit us to develop comments.

Before commenting on the topics of food security, resilience, carbon sequestration, regenerative agriculture, inorganic nitrogen based fertilizer, compost, cover crops and low- and no-till, agricultural land conservation and preservation, and Integrated Pest Management, we preface by saying that everything in the General Plan must be seen through the lens of the global climate and ecological crisis and the need for leadership so that the people of Ventura County are confident that the community response meets some minimum standard of social and environmental justice. Climate

change necessitates an examination of personal values and a shift of mindset about agriculture policy at the local level.

The VC2040 Environmental Impact Report reflects a great deal of this needed shift, but we see omissions in the coverage of existing conditions in the Background Report and in the scope and/or targeting of the goals, policy and programs. There are five programs added to the EIR that are not in the Draft Plan, so we refer to the EIR except where we have comments about the Goal statements in the Plan. The recommendation we hope you take most seriously is to create a separate Goal for Integrated Pest Management.

Planning that matches the climate crisis is vital. This is not clear enough in the Background Report. The most recent report of the Intergovernmental Panel on Climate Change (IPCC) states that the climate problem points *first* to what we do on the land. The USDA Economic Research Service reported on the impacts on prices of food, fiber and energy, and agricultural incomes, as well as the environment. “How farmers respond, or adapt—possibly mediated by policy and technology changes—will ultimately determine the impact of these altered growing conditions on production, natural resources, and food security” Report No ERR-266 “Climate Change and Agricultural Risk Management Into the 21st Century” projects an increase in the cost of the Federal Crop Insurance Program due to greater insured value and yield variability resulting from climate change.

FOOD SECURITY

Lack of secure food system nationally affects local already extreme insecurity. The Union of Concerned Scientists reported in March 2019 that the already highly degraded industrial model of US agriculture—“a model that neglects soil, reduces diversity, and relies too heavily on fertilizers and pesticides”—makes US farms even more vulnerable to the impacts of climate change. Ventura County depends on the rest of the nation and other countries for 85% of its food supply. Our reliance on international markets and international trade leaves our local economy vulnerable to disruptions such as we must anticipate with the Covid-19 coronavirus.

We need to accelerate localizing our food supply as the focus for food security. It would help to delete the false narrative in Goal 8.4 that local farmers are feeding the local people. If there is no food coming or going, farms are not going to be a resource, which is ridiculous in a county that can grow such a diversity of crops throughout the year.

Goal AG-4.1 needs to include all agricultural products, not just fresh produce, and real incentives and marketing campaigns will be necessary including benchmarks for increased purchase of local products by institutions. Program B to encourage sales and Program C to identify opportunities to provide local food to county agencies are good, but they will need to be stronger. A more aggressive set of programs will be necessary to promote markets for local agricultural products to achieve the food security goal.

It is unacceptable to only “identify opportunities...to the extent feasible” to increase county procurement of local products. Feasibility is a matter of where the County decides to invest. Food security is such a priority goal that the county must invest increasingly year by year in local farmers to stimulate a market signal toward localizing our food supply.

Program F in the EIR is excellent to study and remove barriers to farm stands. The program must specifically aim to help Ventura County farmers sell their products in the county and be able to compete with farm stand operators selling products from the San Joaquin Valley, Mexico and elsewhere. Program G to study the “Farm to Front Door” business model ignores many other possible business models to connect producers and consumers and should be rewritten to be more general.

RESILIENCE

Resilience starts with farmers being informed about the climate modeling and adopting practices that increase biodiversity and enrich soil to hold carbon and water. Ventura County hired scientists to run climate models that show the changes in patterns of rainfall, drought, and extreme weather events and how that is connected to wildfires. The modeling is not found with enough detail in the VC2040 Background Report to help farmers and their advisers and representatives understand what’s ahead and why a shift in mindset about goals and effective policies and programs are needed that mitigate the climate impacts.

The Agricultural Resilience goal has one policy AG-6. 2. The plan implies that resilience can be achieved only by crop selection. Neither the goal nor the policy covers the necessity to build soil and water-holding capacity and penetration, increase biodiversity and improve the watershed to hold storm water onsite. Program O in the EIR (Program N in the Draft Policy) refers to reduced tillage but the entire policy and program should be rewritten to assure development of the full scope of important resilience strategies.

INCREASING SOIL CARBON

Carbon sequestration is a moral imperative as well as the centerpiece of resilience. The draft policy to encourage and support carbon farming is not explicit enough about the contribution farmers can make by focused effort to increase soil carbon for climate mitigation.

The California Air Resources Board is working with agencies at local levels to develop measures as outlined in Scoping Plan update and governor's Executive Order B-30-15 to reduce GHG emissions toward net carbon sequestration by California's agricultural sector. The governor's 2030 targets for GHG emission reductions focus on the role played by farmland and soil in the carbon cycle. Research is being done regarding how much GHG is being emitted and how much can be sequestered by California's agricultural lands. The words “when feasible” should be deleted from Policy AG-5. 5 and Program L and replaced by a policy and program to develop meaningful incentives.

A serious flaw in the state Healthy Soils Program is the refusal to allow applications by farmers that have previously done practices on their farm to increase soil carbon. Farmers learn most from other farmers. Our early adopters should be supported to continue to do on-farm experimentation with multi-pronged and innovative practices that to increase their soil carbon and other benefits. The County should create a program complementary to the state program to support exemplary farmers to expand local experiences with carbon sequestration even though they are disqualified (because they are innovators) from the state Greenhouse Gas Reduction Fund programs.

REGENERATIVE AGRICULTURE

Regenerative practices are essential for farmland preservation as well as resilience and food security, whether or not you use that term. The Planning Commission and the Board approved the addition of the word regenerative to the AG-5 goal ‘Sustainable Farming and Ranching’. The term does not appear in the draft. Goals inherent in the word regenerative are not covered in the draft policy or programs—**to increase biodiversity and enrich soils to hold more carbon.** Increasing soil carbon and above-ground biomass may be implied by use of the term ‘Carbon Farming’ but these outcomes should be explicit.

In contrast with regenerative practices, what people understand about sustainable practices does not necessarily include increasing soil carbon and above-ground biomass. The USDA definition of sustainable agriculture: “Make the most efficient use of nonrenewable resources and on-farm resources and integrate, where appropriate, natural biological cycles and controls. Sustain the economic viability of farm operations. Enhance the quality of life for farmers and society as a whole.” Organic farming used to require soil as the growing medium, but not any longer. Using the term “truly sustainable” as in the draft goal still does not assure the features of regenerative agriculture encompassing a robust response to climate change by mitigating greenhouse gas emissions. Prohibiting the use of the word regenerative results in a loss of meaningful guidance for facing today’s challenges. It can be made up for in Goal 5 by at least assuring in the policies and programs its key features of increasing biodiversity, enriching soils in ways that progressively increase soil carbon, increasing above-ground biomass, and improving watersheds.

Biodiversity here refers to everything from soil microbes to plant roots in the soil to above-ground cropping to include 1 to 5% planted for beneficial insect habitat, to include as many native plants as possible. Other practices to increase biodiversity are crop rotation, perennial mowed cover crop in orchards, agroforestry, silvopasture, and interplanting multiple species or varieties of crops. Not only does biodiversity enhance biological function, especially that of carbon sequestration and nutrient cycling, and improve resistance to all risks from diseases to floods, it also improves economic stability by spreading economic risk and buffering against pest invasions and extreme weather events.

INORGANIC NITROGEN BASED FERTILIZERS

Inorganic nitrogen contributes to greenhouse gas emissions and is often unnecessary when regenerative practices are used. The energy used to manufacture and transport artificial N and phosphate fertilizers are major contributors to climate change. Research in pasture and cover crops show fertility is achievable with no nitrogen inputs, artificial or biological. The greater the biodiversity the greater the carbon sequestration, nitrogen fixation, and other nutrient cycling. There is misinformation being shared by trusted experts about the potential to increase soil carbon on Ventura County farms. Research shows that all nutrients, including phosphorus, calcium, and sulfur, as well as nitrogen, are available in soils and can be mobilized by growing the microbial diversity via the “liquid carbon pathway” fed by photosynthesis by a diversity of growing plants. Research and demonstration of this kind should be carried out, particularly in our orchards, vineyards, and other perennial crops.

It is unacceptable as proposed in Policy AG-5.1 to simply “encourage reduced fertilizer use and use of compost and enhanced efficiency fertilizers.” This policy disregards the most cost-effective Best Management Practices to reduce inorganic nitrogen fertilizer use by cover cropping and crop rotation.

The climate mitigation potential as well as the feasibility and the co-benefits associated with avoiding inorganic nitrogen suggest that AG-5.1 should be changed from ‘shall encourage’ to ‘shall study, monitor and set benchmarks’ for reducing use of inorganic nitrogen while encouraging the organic fertility approaches described on page 9-32 of the Background Report. Goals for reduction must show up in the GHG inventory. The inventory reflects no anticipated decrease in use of artificial nitrogen fertilizer for the next 20 years, one of many errors and omissions in the inventory.

COVER CROPS AND LOW- AND NO-TILL

Cover cropping is a Best Management Practice for fertility that should be included in Program H in the EIR. Keeping soil covered prevents loss of soils to wind and water erosion. The benefits for food security, resilience and farmland conservation and preservation are so great that Program H should include incentives for cover cropping and crop rotation that builds soil nitrogen to avoid the need for inorganic nitrogen inputs, build soil carbon, hold water, and protect from erosion.

A program for equipment sharing would help achieve adoption of low- and no-till farming. Farmers need the right size and adaptation of no-till seeders and transplanters for planting into cover crops, flammers and roller crimpers, flails and/or subsurface cutting equipment to be able to keep the ground covered, lay cover crops down, and enable planting and cultivation with minimum soil disturbance. The program should employ a fabricator to work with growers to modify or build the equipment needed to carry out low- and no-till farming.

COMPOST

Application of compost and compost tea or extract can kickstart increases in soil carbon. This is what is commonly promoted as ‘carbon farming’. The County must maximize the availability and use of compost. The County must go beyond the incentives provided by the state Healthy Soils Program and incentivize effective use of compost teas and extracts as well as compost, because when composting is fully implemented there will not be enough compost to support Ventura County land management. There are proven benefits from inoculations with extracts and teas that have not met the state’s accountability criteria for the Greenhouse Gas Reduction Fund grants.

The Background Report should include a description of the expanding expertise and experiences in the County to scale small-scale on-site composting, the application of extracts and brewing of custom blends of compost tea. The community organizing by the Center for Regenerative Agriculture in cooperation with Patagonia employees and Once Upon a Watershed is scalable. A plan for composting food waste should include studying the barriers and maximizing areawide and on-site composting for use by farmers and landscapers. We recommend fast-tracking project approvals and county investment in operations to compost food waste and municipal waste. Compost might be used as a reward for those who follow regenerative farm plans that increase soil carbon.

AGRICULTURAL LAND PROTECTION AND PRESERVATION

Agricultural land protection and preservation depends on development of regenerative farming practices. Some “right-to-farm” issues are often moot when regenerative practices are employed. There may still be noise and odor impacts, but pesticides and dust need not be issues. Food safety issues can be managed. Practices that will best assure financially successful farms are not necessarily incompatible with urban areas or existing communities. It may be an economic advantage to develop compatibility with other land uses because, in the end, landowners have more good financial options when they care for their land using compatible regenerative practices. Otherwise, there is little chance that farmland could be dedicated to agricultural conservation easements. Farmland can only be worth conserving if the land manager increases the biodiversity, enriches the soil to hold carbon and improves the watershed. Furthermore, the most financially stable and potentially profitable farms will increasingly be connected to local markets and be patronized by a community that values their use of organic and/or regenerative practices.

As the most certain way to preserve agricultural land, the General Plan should create baselines and goals and targets for carbon sequestration that is an indicator of the value of farmland, with its co-benefits of preventing pest and disease, erosion and nutrient and water loss prevention, and increasing resilience to drought, flooding and resilience to temperature extremes. If the “right-to-farm” implies that Prime and Important Farmland soil is laid bare, compacted and/or regularly tilled, and exposed to toxic inputs including herbicides, synthetic fertilizer causing it to be devoid of life and subject to erosion and crop failure under extreme weather conditions, then there is no land preservation policy able to save it from being abandoned or sold for development.

INTEGRATED PEST MANAGEMENT

Integrated Pest Management (IPM) policy must be the only pest management policy in the plan and it must be promoted as a system for all sectors, not just a set of practices for farmers. As the University of California definition states, IPM aims to prevent pests and diseases. This is achieved first by healthy plants ideally and then with selection of plants resistant to pests and diseases. Next, healthy plants are achieved by enhanced soil and resulting water holding capacity and fertility and cultural practices tailored to the site, the crop and the seasonal conditions, including habitat enhancement and biodiversity to support naturally occurring beneficial insects and pollinators. IPM is characterized by careful monitoring and avoiding toxic pesticides that disrupt the natural enemy complex that keeps pests below a level that creates economic damage.

IPM is often viewed as a substitution of a more toxic pesticide with a less toxic pesticide—a less disruptive silver bullet. This ignores the foremost feature of IPM which is that it is a system that aims to **prevent** pests and disease. The Agriculture Commission does not currently employ expertise in ecologically systems-based IPM in order to be able to have discussion with applicants about alternatives to pesticides. They have said that they do not see it as their role to advise applicants on alternatives. In our experience it does not appear that applicants are motivated to seriously consider alternatives to toxic pesticides. If the Ag Commission accepts without question whatever shows in the “Alternatives Considered” box on the application form and low risk alternatives are not considered, the process is of no benefit to the public.

One of the barriers to consideration of alternatives is that the most effective alternatives, such as biological control, require earlier lead times and more proactive and multi-pronged strategies than the

use of pesticides. The best alternatives to pesticides require attention to soil building and crop plans that forecast insect movement in the farmscape, in other words systems thinking rather than the common replacement of an organic pesticide for higher risk pesticide.

The Background Report and the EIR omit reference to state legal requirements for the consideration of alternatives and cumulative effects before an applicant is approved to use a regulated pesticide. Pest Control Advisers who represent pesticide companies often do not understand or recommend IPM approaches to pest management. They have a conflict of interest, being paid a commission when they sell pesticides.

Pest Control Advisers who do **not** represent pesticide companies also are not materially incentivized to recommend many IPM practices because it usually requires more advanced agroecological knowledge and experience, and involves more frequent scouting, uncertainty, risk, and complex judgments about economic thresholds. Everything in the existing culture and incentives related to pest management advising and pesticide use applications favors the decision to use pesticides and conclude that there are no alternatives. There is no enforcement of the law over this decision-making process. These existing conditions highlight the need for the Agriculture Commission and the Cooperative Extension to somehow create learning opportunities about ecologically based Integrated Pest Management as a systems approach prioritizing pest and disease prevention.

Policy and programs are needed that lead the entire community of regulators, consultants, farmers and consumers along the Roadmap for Integrated Pest Management in the shift of mindset about pest management described on page 11 that flips the risks and incentives to favor the most effective alternatives that keep pests and disease below economic thresholds.

While developing protocols for guidance, discussion, and documentation of the consideration of alternatives within the definition of IPM, at the very minimum there must be a framework for analyzing cumulative effects of more than one aerial or vapor-borne pesticide and the effects from pesticides used in a non-attainment area for other air pollutants. There is at least one scientifically documented case study in the county of the failure to consider cumulative effects and other cases where studies are urgently needed as a result of the calendar spraying for Asian citrus psyllid.

The policy and programs relating IPM to the general public should also look deeper to support the shift in mindset described in the Roadmap to IPM. It is just scraping the surface “to provide information on IPM and agriculture produces and practices” as stated in Policy AG 3.3. IPM policies should be placed under a separate new goal with policies aligned with the state Roadmap for Integrated Pest Management recommendations. See at https://www.cdpr.ca.gov/docs/pestmgt/ipm_roadmap.pdf

Excerpting ideas from pages 16 and 17 of the Roadmap, for example:

- a. **Hire an IPM coordinator and revive the county’s IPM Committee** with county public participation to promoting IPM practices
- b. **Drive demand for IPM in the value chain** by coordinating efforts with key organizations to link IPM and regenerative and sustainable agriculture initiatives with retail brands and raise awareness among commodities and allied groups such as packers and shippers, retailers, and trade partners

- c. **Participate in speeding up IPM innovation** through innovation hubs and on-farm research of ecologically based preventive strategies
- d. **Invest in trusted messengers** by collaborating with community-based organizations to facilitate field worker training on IPM and highlight ways they can be IPM leaders in the community as partners and storytellers, creating opportunities through environmental justice to address pest and pesticide issues for low-income households and neighborhoods, and expanding educational offerings in Spanish and Mixtec with culturally appropriate materials
- e. **Profit from frontline knowledge of field workers and municipal applicators** to improve early detection of pests, recommend lower risk approaches, and use safe practices in the workplace
- f. **Strengthen the public's capacity to understand** pests, pesticides and IPM by featuring IPM in training programs including STEM in schools, community colleges, 4-H, Master Gardeners, senior citizens' groups and others, teach consumers about pest prevention using IPM examples, promote positive public announcements with using IPM in core messages, and include identification of pesticide poisoning in continuing education of health professionals
- g. **Make practitioners more effective voices** for IPM by training frontline workers in agriculture, landscape and structural IPM
- h. **Leverage non-traditional resources** for IPM by working with Chumash and Mexican indigenous leaders to learn and expand the community's awareness about native wisdom that relates to IPM
- i. **Strengthen capacity of practitioners** to use more true IPM by supporting on-farm demonstrations and farmer-to-farmer field days and establishing training in non-agricultural settings e.g., restaurant and assisted-living workers, landscapers, etc.
- j. **Help redesign the retail IPM process** with programs to support retailers to educate consumers about responsible use of pesticides, limiting availability of high risk pesticides in the marketplace to trained and licensed professionals, and creating partnerships with local organizations such as Ocean Friendly Gardens to provide education and resources for consumers. An excellent example is the Our Water; Our World program.

Sincerely,

February 27, 2020

Dear Susan Curtis,

Our comments are about the Draft Environmental Impact Analysis of the Agriculture Element of the VC2040 General Plan. We have serious concerns about other chapters, especially Water Resources, but time does not permit us to develop comments.

Before commenting on the topics of food security, resilience, carbon sequestration, regenerative agriculture, inorganic nitrogen based fertilizer, compost, cover crops and low- and no-till, agricultural land conservation and preservation, and Integrated Pest Management, we preface by saying that everything in the General Plan must be seen through the lens of the global climate and ecological crisis and the need for leadership so that the people of Ventura County are confident that the community response meets some minimum standard of social and environmental justice. Climate change necessitates an examination of personal values and a shift of mindset about agriculture policy at the local level.

The VC2040 Environmental Impact Report reflects a great deal of this needed shift, but we see omissions in the coverage of existing conditions in the Background Report and in the scope and/or targeting of the goals, policy and programs. There are five programs added to the EIR that are not in the Draft Plan, so we refer to the EIR except where we have comments about the Goal statements in the Plan. The recommendation we hope you take most seriously is to create a separate Goal for Integrated Pest Management.

Planning that matches the climate crisis is vital. This is not clear enough in the Background Report. The most recent report of the Intergovernmental Panel on Climate Change (IPCC) states that the climate problem points *first* to what we do on the land. The USDA Economic Research Service reported on the impacts on prices of food, fiber and energy, and agricultural incomes, as well as the environment. “How farmers respond, or adapt—possibly mediated by policy and technology changes—will ultimately determine the impact of these altered growing conditions on production, natural resources, and food security” Report No ERR-266 “Climate Change and Agricultural Risk Management Into the 21st Century” projects an increase in the cost of the Federal Crop Insurance Program due to greater insured value and yield variability resulting from climate change.

FOOD SECURITY

Lack of secure food system nationally affects local already extreme insecurity.

The Union of Concerned Scientists reported in March 2019 that the already highly degraded industrial model of US agriculture—“a model that neglects soil, reduces

diversity, and relies too heavily on fertilizers and pesticides”—makes US farms even more vulnerable to the impacts of climate change. Ventura County depends on the rest of the nation and other countries for 85% of its food supply. Our reliance on international markets and international trade leaves our local economy vulnerable to disruptions such as we must anticipate with the Covid-19 coronavirus.

We need to accelerate localizing our food supply as the focus for food security. It would help to delete the false narrative in Goal 8.4 that local farmers are feeding the local people. If there is no food coming or going, farms are not going to be a resource, which is ridiculous in a county that can grow such a diversity of crops throughout the year.

Goal AG-4.1 needs to include all agricultural products, not just fresh produce, and real incentives and marketing campaigns will be necessary including benchmarks for increased purchase of local products by institutions. Program B to encourage sales and Program C to identify opportunities to provide local food to county agencies are good, but they will need to be stronger. A more aggressive set of programs will be necessary to promote markets for local agricultural products to achieve the food security goal.

It is unacceptable to only “identify opportunities...to the extent feasible” to increase county procurement of local products. Feasibility is a matter of where the County decides to invest. Food security is such a priority goal that the county must invest increasingly year by year in local farmers to stimulate a market signal toward localizing our food supply.

Program F in the EIR is excellent to study and remove barriers to farm stands. The program must specifically aim to help Ventura County farmers sell their products in the county and be able to compete with farm stand operators selling products from the San Joaquin Valley, Mexico and elsewhere. Program G to study the “Farm to Front Door” business model ignores many other possible business models to connect producers and consumers and should be rewritten to be more general.

RESILIENCE

Resilience starts with farmers being informed about the climate modeling and adopting practices that increase biodiversity and enrich soil to hold carbon and water. Ventura County hired scientists to run climate models that show the changes in patterns of rainfall, drought, and extreme weather events and how that is connected to wildfires. The modeling is not found with enough detail in the VC2040 Background Report to help farmers and their advisers and representatives understand what’s ahead and why a shift in mindset about goals and effective policies and programs are needed that mitigate the climate impacts.

The Agricultural Resilience goal has one policy AG-6. 2. The plan implies that resilience can be achieved only by crop selection. Neither the goal nor the policy covers the necessity to build soil and water-holding capacity and penetration, increase biodiversity and improve the watershed to hold storm water onsite. Program O in the EIR (Program N in the Draft Policy) refers to reduced tillage but the entire policy and program should be rewritten to assure development of the full scope of important resilience strategies.

INCREASING SOIL CARBON

Carbon sequestration is a moral imperative as well as the centerpiece of resilience. The draft policy to encourage and support carbon farming is not explicit enough about the contribution farmers can make by focused effort to increase soil carbon for climate mitigation.

The California Air Resources Board is working with agencies at local levels to develop measures as outlined in Scoping Plan update and governor's Executive Order B-30-15 to reduce GHG emissions toward net carbon sequestration by California's agricultural sector. The governor's 2030 targets for GHG emission reductions focus on the role played by farmland and soil in the carbon cycle. Research is being done regarding how much GHG is being emitted and how much can be sequestered by California's agricultural lands. The words "when feasible" should be deleted from Policy AG-5. 5 and Program L and replaced by a policy and program to develop meaningful incentives.

A serious flaw in the state Healthy Soils Program is the refusal to allow applications by farmers that have previously done practices on their farm to increase soil carbon. Farmers learn most from other farmers. Our early adopters should be supported to continue to do on-farm experimentation with multi-pronged and innovative practices that to increase their soil carbon and other benefits. The County should create a program complementary to the state program to support exemplary farmers to expand local experiences with carbon sequestration even though they are disqualified (because they are innovators) from the state Greenhouse Gas Reduction Fund programs.

REGENERATIVE AGRICULTURE

Regenerative practices are essential for farmland preservation as well as resilience and food security, whether or not you use that term. The Planning Commission and the Board approved the addition of the word regenerative to the AG-5 goal 'Sustainable Farming and Ranching'. The term does not appear in the draft. Goals inherent in the word regenerative are not covered in the draft policy or programs—**to increase biodiversity and enrich soils to hold more carbon.** Increasing soil carbon and above-ground biomass may be implied by use of the term 'Carbon Farming' but these outcomes should be explicit.

In contrast with regenerative practices, what people understand about sustainable practices does not necessarily include increasing soil carbon and above-ground biomass. The USDA definition of sustainable agriculture: “Make the most efficient use of nonrenewable resources and on-farm resources and integrate, where appropriate, natural biological cycles and controls. Sustain the economic viability of farm operations. Enhance the quality of life for farmers and society as a whole.” Organic farming used to require soil as the growing medium, but not any longer. Using the term “truly sustainable” as in the draft goal still does not assure the features of regenerative agriculture encompassing a robust response to climate change by mitigating greenhouse gas emissions. Prohibiting the use of the word regenerative results in a loss of meaningful guidance for facing today’s challenges. It can be made up for in Goal 5 by at least assuring in the policies and programs its key features of increasing biodiversity, enriching soils in ways that progressively increase soil carbon, increasing above-ground biomass, and improving watersheds.

Biodiversity here refers to everything from soil microbes to plant roots in the soil to above-ground cropping to include 1 to 5% planted for beneficial insect habitat, to include as many native plants as possible. Other practices to increase biodiversity are crop rotation, perennial mowed cover crop in orchards, agroforestry, silvopasture, and interplanting multiple species or varieties of crops. Not only does biodiversity enhance biological function, especially that of carbon sequestration and nutrient cycling, and improve resistance to all risks from diseases to floods, it also improves economic stability by spreading economic risk and buffering against pest invasions and extreme weather events.

INORGANIC NITROGEN BASED FERTILIZERS

Inorganic nitrogen contributes to greenhouse gas emissions and is often unnecessary when regenerative practices are used. The energy used to manufacture and transport artificial N and phosphate fertilizers are major contributors to climate change. Research in pasture and cover crops show fertility is achievable with no nitrogen inputs, artificial or biological. The greater the biodiversity the greater the carbon sequestration, nitrogen fixation, and other nutrient cycling. There is misinformation being shared by trusted experts about the potential to increase soil carbon on Ventura County farms. Research shows that all nutrients, including phosphorus, calcium, and sulfur, as well as nitrogen, are available in soils and can be mobilized by growing the microbial diversity via the “liquid carbon pathway” fed by photosynthesis by a diversity of growing plants. Research and demonstration of this kind should be carried out, particularly in our orchards, vineyards, and other perennial crops.

It is unacceptable as proposed in Policy AG-5.1 to simply “encourage reduced fertilizer use and use of compost and enhanced efficiency fertilizers.” This policy disregards the

most cost-effective Best Management Practices to reduce inorganic nitrogen fertilizer use by cover cropping and crop rotation. The climate mitigation potential as well as the feasibility and the co-benefits associated with avoiding inorganic nitrogen suggest that AG-5.1 should be changed from ‘shall encourage’ to ‘shall study, monitor and set benchmarks’ for reducing use of inorganic nitrogen while encouraging the organic fertility approaches described on page 9-32 of the Background Report. Goals for reduction must show up in the GHG inventory. The inventory reflects no anticipated decrease in use of artificial nitrogen fertilizer for the next 20 years, one of many errors and omissions in the inventory.

COVER CROPS AND LOW- AND NO-TILL

Cover cropping is a Best Management Practice for fertility that should be included in Program H in the EIR. Keeping soil covered prevents loss of soils to wind and water erosion. The benefits for food security, resilience and farmland conservation and preservation are so great that Program H should include incentives for cover cropping and crop rotation that builds soil nitrogen to avoid the need for inorganic nitrogen inputs, build soil carbon, hold water, and protect from erosion.

A program for equipment sharing would help achieve adoption of low- and no-till farming. Farmers need the right size and adaptation of no-till seeders and transplanters for planting into cover crops, flammers and roller crimpers, flails and/or subsurface cutting equipment to be able to keep the ground covered, lay cover crops down, and enable planting and cultivation with minimum soil disturbance. The program should employ a fabricator to work with growers to modify or build the equipment needed to carry out low- and no-till farming.

COMPOST

Application of compost and compost tea or extract can kickstart increases in soil carbon. This is what is commonly promoted as ‘carbon farming’. The County must maximize the availability and use of compost. The County must go beyond the incentives provided by the state Healthy Soils Program and incentivize effective use of compost teas and extracts as well as compost, because when composting is fully implemented there will not be enough compost to support Ventura County land management. There are proven benefits from inoculations with extracts and teas that have not met the state’s accountability criteria for the Greenhouse Gas Reduction Fund grants.

The Background Report should include a description of the expanding expertise and experiences in the County to scale small-scale on-site composting, the application of extracts and brewing of custom blends of compost tea. The community organizing by the Center for Regenerative Agriculture in cooperation with Patagonia employees and

Once Upon a Watershed is scalable. A plan for composting food waste should include studying the barriers and maximizing areawide and on-site composting for use by farmers and landscapers. We recommend fast-tracking project approvals and county investment in operations to compost food waste and municipal waste. Compost might be used as a reward for those who follow regenerative farm plans that increase soil carbon.

AGRICULTURAL LAND PROTECTION AND PRESERVATION

Agricultural land protection and preservation depends on development of regenerative farming practices. Some “right-to-farm” issues are often moot when regenerative practices are employed. There may still be noise and odor impacts, but pesticides and dust need not be issues. Food safety issues can be managed. Practices that will best assure financially successful farms are not necessarily incompatible with urban areas or existing communities. It may be an economic advantage to develop compatibility with other land uses because, in the end, landowners have more good financial options when they care for their land using compatible regenerative practices. Otherwise, there is little chance that farmland could be dedicated to agricultural conservation easements. Farmland can only be worth conserving if the land manager increases the biodiversity, enriches the soil to hold carbon and improves the watershed. Furthermore, the most financially stable and potentially profitable farms will increasingly be connected to local markets and be patronized by a community that values their use of organic and/or regenerative practices.

As the most certain way to preserve agricultural land, the General Plan should create baselines and goals and targets for carbon sequestration that is an indicator of the value of farmland, with its co-benefits of preventing pest and disease, erosion and nutrient and water loss prevention, and increasing resilience to drought, flooding and resilience to temperature extremes. If the “right-to-farm” implies that Prime and Important Farmland soil is laid bare, compacted and/or regularly tilled, and exposed to toxic inputs including herbicides, synthetic fertilizer causing it to be devoid of life and subject to erosion and crop failure under extreme weather conditions, then there is no land preservation policy able to save it from being abandoned or sold for development.

INTEGRATED PEST MANAGEMENT

Integrated Pest Management (IPM) policy must be the only pest management policy in the plan and it must be promoted as a system for all sectors, not just a set of practices for farmers. As the University of California definition states, IPM aims to prevent pests and diseases. This is achieved first by healthy plants ideally and then with selection of plants resistant to pests and diseases. Next, healthy plants are achieved by enhanced soil and resulting water holding capacity and fertility and cultural

practices tailored to the site, the crop and the seasonal conditions, including habitat enhancement and biodiversity to support naturally occurring beneficial insects and pollinators. IPM is characterized by careful monitoring and avoiding toxic pesticides that disrupt the natural enemy complex that keeps pests below a level that creates economic damage.

IPM is often viewed as a substitution of a more toxic pesticide with a less toxic pesticide—a less disruptive silver bullet. This ignores the foremost feature of IPM which is that it is a system that aims to **prevent** pests and disease. The Agriculture Commission does not currently employ expertise in ecologically systems-based IPM in order to be able to have discussion with applicants about alternatives to pesticides. They have said that they do not see it as their role to advise applicants on alternatives. In our experience it does not appear that applicants are motivated to seriously consider alternatives to toxic pesticides. If the Ag Commission accepts without question whatever shows in the “Alternatives Considered” box on the application form and low risk alternatives are not considered, the process is of no benefit to the public.

One of the barriers to consideration of alternatives is that the most effective alternatives, such as biological control, require earlier lead times and more proactive and multi-pronged strategies than the use of pesticides. The best alternatives to pesticides require attention to soil building and crop plans that forecast insect movement in the farmscape, in other words systems thinking rather than the common replacement of an organic pesticide for higher risk pesticide.

The Background Report and the EIR omit reference to state legal requirements for the consideration of alternatives and cumulative effects before an applicant is approved to use a regulated pesticide. Pest Control Advisers who represent pesticide companies often do not understand or recommend IPM approaches to pest management. They have a conflict of interest, being paid a commission when they sell pesticides.

Pest Control Advisers who do **not** represent pesticide companies also are not materially incentivized to recommend many IPM practices because it usually requires more advanced agroecological knowledge and experience, and involves more frequent scouting, uncertainty, risk, and complex judgments about economic thresholds. Everything in the existing culture and incentives related to pest management advising and pesticide use applications favors the decision to use pesticides and conclude that there are no alternatives. There is no enforcement of the law over this decision-making process. These existing conditions highlight the need for the Agriculture Commission and the Cooperative Extension to somehow create learning opportunities about ecologically based Integrated Pest Management as a systems approach prioritizing pest and disease prevention.

Policy and programs are needed that lead the entire community of regulators, consultants, farmers and consumers along the Roadmap for Integrated Pest Management in the shift of mindset about pest management described on page 11 that flips the risks and incentives to favor the most effective alternatives that keep pests and disease below economic thresholds.

While developing protocols for guidance, discussion, and documentation of the consideration of alternatives within the definition of IPM, at the very minimum there must be a framework for analyzing cumulative effects of more than one aerial or vapor-borne pesticide and the effects from pesticides used in a non-attainment area for other air pollutants. There is at least one scientifically documented case study in the county of the failure to consider cumulative effects and other cases where studies are urgently needed as a result of the calendar spraying for Asian citrus psyllid.

The policy and programs relating IPM to the general public should also look deeper to support the shift in mindset described in the Roadmap to IPM. It is just scraping the surface “to provide information on IPM and agriculture produces and practices” as stated in Policy AG 3.3. IPM policies should be placed under a separate new goal with policies aligned with the state Roadmap for Integrated Pest Management recommendations. See at https://www.cdpr.ca.gov/docs/pestmgt/ipm_roadmap.pdf

Excerpting ideas from pages 16 and 17 of the Roadmap, for example:

- a. **Hire an IPM coordinator and revive the county’s IPM Committee** with county public participation to promoting IPM practices
- b. **Drive demand for IPM in the value chain** by coordinating efforts with key organizations to link IPM and regenerative and sustainable agriculture initiatives with retail brands and raise awareness among commodities and allied groups such as packers and shippers, retailers, and trade partners
- c. **Participate in speeding up IPM innovation** through innovation hubs and on-farm research of ecologically based preventive strategies
- d. **Invest in trusted messengers** by collaborating with community-based organizations to facilitate field worker training on IPM and highlight ways they can be IPM leaders in the community as partners and storytellers, creating opportunities through environmental justice to address pest and pesticide issues for low-income households and neighborhoods, and expanding educational offerings in Spanish and Mixtec with culturally appropriate materials
- e. **Profit from frontline knowledge of field workers and municipal applicators** to improve early detection of pests, recommend lower risk approaches, and use safe practices in the workplace
- f. **Strengthen the public’s capacity to understand** pests, pesticides and IPM by featuring IPM in training programs including STEM in schools, community colleges, 4-H, Master Gardeners, senior citizens’ groups and others, teach consumers about pest prevention using IPM examples, promote positive public

- announcements with using IPM in core messages, and include identification of pesticide poisoning in continuing education of health professionals
- g. **Make practitioners more effective voices** for IPM by training frontline workers in agriculture, landscape and structural IPM
 - h. **Leverage non-traditional resources** for IPM by working with Chumash and Mexican indigenous leaders to learn and expand the community's awareness about native wisdom that relates to IPM
 - i. **Strengthen capacity of practitioners** to use more true IPM by supporting on-farm demonstrations and farmer-to-farmer field days and establishing training in non-agricultural settings e.g., restaurant and assisted-living workers, landscapers, etc.
 - j. **Help redesign the retail IPM process** with programs to support retailers to educate consumers about responsible use of pesticides, limiting availability of high risk pesticides in the marketplace to trained and licensed professionals, and creating partnerships with local organizations such as Ocean Friendly Gardens to provide education and resources for consumers. An excellent example is the Our Water; Our World program.

2040 General Plan Draft EIR Comment:

The County rushed to complete the EIR. It is too important to be done haphazardly and contain gross flaws that will impact our County so drastically.

Just a couple of the issues:

CEQA requires that proposed mitigation be both technically and economically feasible. The County's proposed mitigation measures are **infeasible**. One mitigation measure will require small development projects to purchase farmland to preserve in perpetuity. But the County didn't analyze the costs or indicate who would manage these small ag preservation parcels.

CEQA says that the mitigation cannot make the impacts worse. Shortage of farm worker housing was identified as one of the most significant issues facing agriculture in Ventura County. But mitigation proposed by the County will effectively block future farm worker housing, because these projects will bear the costs of land acquisition for preservation!

Please do what is right for Ventura County and take the time to correct and re-circulate the EIR.

Subject: 2040 General Plan Draft EIR Comment

Dear Ms. Curtis: The EIR is based on incomplete analysis of policies, contains several false and ill-advised policies, and fails to understand key challenges related to Ventura County.

Some of the issues are:

1. CEQA requires that the EIR contain enough detailed information to allow the reader to understand and evaluate the County's impact analysis. But the EIR and its 1000-page Background Report are filled with errors, vague statements, and outdated information. All information in the Agricultural Chapter is older than 2015! The maps in the EIR and the Background Report are such poor resolution and detail that some are blurry and illegible.
2. CEQA requires that both direct and indirect impacts be analyzed. Yet the County failed to analyze indirect impacts (complaints, competition for water supplies, theft and vandalism, etc.) on agricultural land from increased development and more urban-ag interface, because the County assumes that the Right-to-Farm Ordinance will prevent any impacts on agriculture that may occur from urban-property owner complaints.
3. CEQA says that all policies that may cause impacts to ag lands must be evaluated. But the County failed to analyze or even discuss the policies in the General Plan that will increase farming operational costs (converting ag equipment to electric, requiring all electric water pumps, increasing costs for water supply, etc.).

Please do the correct thing for Ventura County and take the time to correct and recirculate the EIR!

RE: Ventura County 2040 General Plan Update
Vic. Countywide
SCH # 2019011026
Ref. GTS # VEM-2017-00228AL-NOP
GTS # VEN-2017-00388AL-DEIR

Dear Ms. Curtis:

Thank you for including the California Department of Transportation (Caltrans) in the environmental review process for the above referenced project. The proposed project is a comprehensive update of the County of Ventura General Plan, also known as the 2040 General Plan. The 2040 General Plan will set forth the County's vision of its future and identify the goals, policies, and implementation programs that will guide future decisions concerning a variety of issues, including but not limited to land use, climate change, agriculture, transportation, hazards, public facilities, health and safety, environmental justice, and resource conservation out to the year 2040.

The mission of Caltrans is to provide a safe, sustainable, integrated and efficient transportation system to enhance California's economy and livability. Senate Bill 743 (2013) mandated that CEQA review of transportation impacts of proposed development be modified by using Vehicle Miles Traveled (VMT) as the primary metric in identifying transportation impacts for all future development projects. For future project, you may reference to The Governor's Office of Planning and Research (OPR) for more information.

<http://opr.ca.gov/ceqa/updates/guidelines/>

The Lead Agency has provided a VMT analysis for this project and using 2012 Baseline Model, 2040 Ventura County General Plan Land Use Model, 2040 VCTC and 2040 SBCAG travel demand model. For further review and feedback, it would be helpful if the County can share all models and assumptions with Caltrans to validate the model results (including 2040 General Plan results on page 4.16-24) provided in section 4.16 Transportation and Traffic.

Caltrans is aware of challenges that the region faces in identifying viable solutions to alleviating congestion on State and Local facilities. With limited room to expand vehicular capacity, in general Caltrans concurs the County's policies for future developments that

should incorporate multi-modal and complete streets transportation elements that will actively promote alternatives to car use and better manage existing parking assets and policies for bicycling, pedestrian, and public transit which can allow streets to transport more people in a fixed amount of right-of-way.

We encourage the Lead Agency to integrate transportation and land use in a way that reduces Vehicle Miles Traveled (VMT) and Greenhouse Gas (GHG) emissions by facilitating the provision of more proximate goods and services to shorten trip lengths, and achieve a high level of non-motorized travel and transit use. We also encourage the Lead Agency to evaluate the potential of Transportation Demand Management (TDM) strategies and Intelligent Transportation System (ITS) applications in order to better manage the transportation network, as well as transit service and bicycle or pedestrian connectivity improvements. Moreover, we encourage mixed-use development with smart growth principle to shorten travel distance for different land uses to achieve job-and-housing balance within the County boundary.

We have the following comments and recommendations for the following policies:

Policy CTM-1.7: Pro Rata Share of Improvements. We concur that “the County shall require discretionary development that would generate additional traffic to pay its pro rata share of the cost of added vehicle trips and the costs of necessary improvements to the Regional Road Network pursuant to the County’s Traffic Impact Mitigation Fee Ordinance.” Caltrans recommend the improvements shall include the State facilities identified and approved by both agencies.

Policy CTM-2.9: State Route 118 Improvement in Saticoy Area. When the final list of improvement is approved by Caltrans and Ventura County Transportation Commission (VCTC), we recommend this list be a part of the fair share program in the County’s Traffic Impact Mitigation Fee Ordinance.

Policy CTM-2.19: Safety Metrics. We concur that “the County shall continue to examine and update safety metrics for California Environmental Quality Act (CEQA) impact analysis as appropriate. Option include but are not limited to: queue spill-back at intersections; midblock unprotected crossings; and increased crossing distances.” Caltrans recommend the safety impact analysis shall also include off-ramps, State intersections, and weaving areas on the freeway mainlines. Caltrans will provide separate consultation for any queuing analysis when needed.

Policy CTM-4.1: Reduce Vehicle Miles Traveled (VMT). We concur that “the County shall work with Caltrans and Ventura County Transportation Commission (VCTC) to reduce VMT by...”. We recommend future projects to consider additional Traffic Demand Management (TDM) options referencing to the Federal Highway Administration’s *Integrating Demand Management into the Transportation Planning Process: A Desk Reference* (Chapter 8). The reference is available online at:

<http://www.ops.fhwa.dot.gov/publications/fhwahop12035/fhwahop12035.pdf>

We recommend the County to develop a monitoring program to monitor the effectiveness of TDM or Vehicle Miles Traveled (VMT) Reduction Program.

We would like the County to invite Caltrans to review and to provide consultation/feedback when the County is developing or updating the following Implementation Programs in the future.

- Implementation Program A: Traffic Impact Mitigation Fee Program.**
- Implementation Program B: Initial Study Assessment Guidelines.**
- Implementation Program C: Vehicle Miles Traveled (VMT) Reduction Program.**
- Implementation Program D: Regional Road Network Coordination.**
- Implementation Program L: Master Bicycle Network Plan.**

For Land Use and Community Character Element, we concur “**Policy LU-11.3: Design.** The County shall require new commercial and industrial developments to be designed to be generally compact, grouped and consolidated into functional units providing for sufficient off-street parking and loading facilities, maximize pedestrian and vehicle safety, reduce vehicle miles traveled (VMT), encourage electric vehicle charging, and minimize land use conflicts and traffic congestion. The County shall require that commercial and industrial discretionary development is designed to provide adequate buffering (e.g., walls, landscaping, setbacks) and operational conditions (e.g., noise, glare, and odors) on adjoining and adjacent residential area.” Again, this is where we would encourage the County to promote mixed-use development with smart growth principle to shorten travel distance for different land uses to achieve job-and-housing balance within the County boundary.

Policy HAZ-10.8: Alternative Transportation Modes. We concur that “the County shall promote alternative modes of transportation that reduce single-occupancy vehicle (SOV) travel and enhance “last-mile” transportation option to improve air quality.” We recommend

the County to develop a program to promote the alternative modes of transportation for new development projects.

For Mitigation Measure CTM-3: Revised Implementation Program CTM-C: Vehicle Miles Traveled (VMT) Reduction Program, we concur that "During implementation of the 2040 General Plan, the County shall review and update the VMT Reduction Program as warranted to provide additional mitigations and Programs." Again, we recommend the County to include Caltrans in the review and update process whenever is available.

For Mitigation Measure CTM-4: New Implementation Program CTM-X; Updated Traffic Impact Fee Mitigation Program, we concur that "the County shall require that development which adds traffic to roadways traversing within a County designated substandard roadway impact area contribute the fair share costs of any safety counter-measures that improve the safety of the impacted roadways by paying the applicable fees under the County's Traffic Impact Fee mitigation program prior to issuance of Zoning Clearance." Again, we recommend such safety improvements include the State facilities.

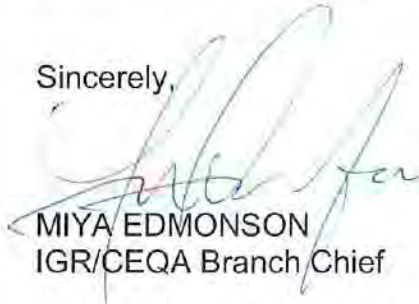

After this mitigation, we understand that "traffic volume would increase on existing roadways already identified as substandard facilities. Substandard roadways must be improved to meet County road standards to mitigate impact significance. Further, analysis of trips added by discretionary development to roadways identified as facilities with high collision/incidence rates must be explored at the project-level to ensure safety standards are met. No other feasible mitigation is available to eliminate safety concerns associated with the identified substandard roadways. Therefore, this impact would remain significant and unavoidable."

On page 5-19 of the 2040 General Plan Draft Environmental Impact Report, we acknowledge that "the VMT impact analysis relies on existing and future growth accommodated through the 2040 General Plan and accounts for the projected growth of the incorporated cities and surrounding counties. Therefore, the transportation and traffic impacts identified in Section 4.16, are inherently cumulative. The VMT and County road standards and safety impacts would remain significant and unavoidable even with mitigation measures due to the increased development, new roadways, and increased numbers of users on the county's transportation system that would result from implementation of the 2040 General Plan. Therefore, the potential for cumulative impacts related to transportation and traffic would be cumulatively significant, and the project would have a considerable contribution." In the end, we recommend the County to work with Caltrans closely for each specific large project in the future to identify safety improvements on the State facilities and also in achieving to reduce VMT with land use balance principle.

Re: 2040 General Plan Environmental Impact Report (EIR)

Dear Mr. Hedrick and Honorable Members of APAC:

Thank you for the opportunity to provide comments following today's presentation by Ventura County Planning staff on the 2040 General Plan EIR.

There are several issues with the 2040 General Plan EIR that CoLAB believes will negatively impact the viability of local agriculture.

Proposed mitigation measure AG-2: The County proposes that any project that either directly or indirectly results in the loss of farmland must obtain and place into perpetual agricultural preservation twice the total of the farmland loss. This mitigation measure is infeasible. Contrary to statements made by County Planning staff today at the APAC meeting, the California Environmental Quality Act (CEQA) requires that all mitigation proposed in an EIR be feasible. CEQA Section 21061.1 defines feasible as “capable of being accomplished in a successful manner within a reasonable period of time,

” (*emphasis added*). All mitigation measures proposed in an EIR must be shown to reduce impacts

and an infeasible mitigation measure, by definition, cannot and will not reduce impacts.

The EIR does not provide evidence of any of the following:

1. 1) Whether there is sufficient land available for purchase/conservation easement for each farmland category;
2. 2) The cost per acre to purchase each category of farmland;
3. 3) The anticipated cost of establishing a conservation easement for each category of farmland;
4. 4) The anticipated cost associated with managing each category of farmland under a conservation easement;
5. 5) The anticipated cost associated with monitoring these mitigation parcels scattered throughout the County and who will bear that cost;
6. 6) Any information that could constitute a “plan” for management of farmland in conservation easements;

February 19, 2020

Ventura County Coalition of Labor, Agriculture and Business / 1672 Donlon Street, Ventura, CA 93003 / 805-633-2260 / info@colabvc.org

Page 2 of 4

7. 7) An analysis of direct and indirect impacts caused by this mitigation measure (including impacts associated with LU compatibility conflicts and increased urban-ag-interface);
8. 8) Whether the smallest possible mitigation acreage required will achieve the minimum to ensure viability of agriculture on the parcel; and

9. 9) Whether the proposed mitigation is in conflict with other ordinances and regulations, such as the County's Zoning Ordinance and the County's minimum lot sizes.

The County is already aware that this proposed mitigation measure is infeasible. On March 24, 2016, at a Local Agency Formation Commission (LAFCo) hearing, Supervisor Linda Parks attempted to establish an "Agricultural Mitigation Measure" through the LAFCo project approval process. The mitigation measure would have required the 1-to-1 purchase of local farmland (half of what is proposed in the 2040 General Plan EIR) to replace farmland that would be impacted by any proposed development. Ventura County Counsel, Michael Walker, informed both LAFCo and Supervisor Parks that the proposed mitigation measure did not meet the standard for economic feasibility, and, for that and other reasons, LAFCo could not adopt Supervisor Park's proposed mitigation measure. He referenced a 2015 legal decision, *City of Irvine v. County of Orange*, in which the Court stated, "the sheer astronomical expense of land supports the finding of the EIR that the purchase of an agricultural conservation easement is a non-starter."

In addition to being infeasible, CoLAB does not believe that this mitigation measure will reduce impacts on agricultural land, as it does not address the actual issues that will impact farmland under the 2040 General Plan: lack of economic sustainability, the increasing regulatory demands on agriculture, increased competition for water resources, and increased compatibility conflicts from development.

Indirect Impacts

The EIR dismisses "indirect impacts" that will occur as a result of implementing the 2040 General Plan as "less than significant."

Page 4.2-13 of the EIR states "AG-2.3 maintains the Right-to-Farm Ordinance to protect agricultural land uses from conflicts with non-agricultural uses, as well as to help land purchasers and residents understand the potential for nuisance, (e.g., dust, noise, odors) that may occur as the natural result of living in or near agricultural areas...These sections of the code protect farmers engaged in agricultural activity from public nuisance claims...This protects the farming community, including Important Farmlands and farms less than 10 acres, from developments that would inhibit their ability to continue agricultural production."

Page 4.2-17 of the EIR states: "Residential growth in areas nearby agricultural lands has the potential to result in land use conflicts. Residential land uses are generally more sensitive and prone to conflict with adjacent agricultural land uses than commercial or industrial land uses. The placement of sensitive land uses, such as residences and schools, nearby classified farmland can negatively impact both uses due to conflict including odor nuisances and noise from agriculture machinery. The countywide Right-to-Farm Ordinance protects existing agricultural and farming operations from conflicts attributed to residential development...**Therefore, the potential for conflicts would be minimal. This impact would be less than significant**" (*emphasis added*).

This is simply not true. Historic and recent County actions have shown that the County has and will continue to create new restrictions and ordinances that have a significant impact on existing agricultural

Ventura County Coalition of Labor, Agriculture and Business / 1672 Donlon Street, Ventura, CA
93003 / 805-633-2260 / info@colabvc.org

Page 3 of 4

and farming operations because of conflicts attributed to residential development. The recent interim

urgency ordinance restricting hemp cultivation is one such example.

Contrary to statements made today by Ventura County Planning staff, an EIR, whether it is labeled as “programmatic” or “project”, must analyze all reasonably foreseeable consequences of the action that is proposed. For the 2040 General Plan EIR, the action proposed is the implementation of all policies and programs within. Therefore, if the implementation of a policy in the 2040 General Plan will result in an impact, that impact must be analyzed. For example, the 2040 General Plan contains land use designation changes that will increase allowable housing density near agricultural land. It is reasonably foreseeable that more houses will create more compatibility conflicts with normal farming operations. The impact of these compatibility conflicts must be addressed in the EIR.

In 2014, the California Court of Appeal stated in a ruling that “[T]he fact that this EIR is labeled a ‘project’ rather than a ‘program’ EIR matters little....Designating an EIR as a program EIR ... does not by itself decrease the level of analysis otherwise required in the EIR. All EIRs must cover the same general content. The level of specificity of an EIR is determined by the nature of the project and the “rule of reason,” rather than any semantic label accorded to the EIR.”

It is CoLAB’s opinion that indirect impacts from increasing urban-ag interface are SIGNIFICANT and cannot be dismissed in the EIR.

Direct and indirect impacts of increased costs

The 2040 General Plan has policies that will increase the costs of normal farming operations. CoLAB believes that the most effective way to minimize conversion of agricultural land to non-agricultural uses is to take active measures to allow farming to remain profitable. And even the County admits that reducing the cost of farming reduces conversion of agricultural land in their discussion of the Williamson Act in Chapter 4.2 of the EIR.

But the County fails to analyze direct and indirect impacts of 2040 General Plan policies that will increase the cost of normal farming operations, such as:

- Policy AG-5.2: Electric- or Renewable-Powered Agricultural Equipment. The County shall encourage and support the transition to electric- or renewable-powered or lower emission agricultural equipment in place of fossil fuel-powered equipment when feasible.
- Policy AG-5.3: Electric- or Renewable-Powered Irrigation Pumps. The County shall encourage farmers to convert fossil fuel-powered irrigation pumps to systems powered by electric or renewable energy sources, such as solar power, and encourage electric utilities to eliminate or reduce standby charges.

Direct and indirect impacts of increased competition for water resources
The County fails to evaluate the impact of increased competition for water resources caused by development allowed in the 2040 General Plan on either the conversion of agricultural land or the loss of agricultural lands through the loss of topsoil.

The EIR states on page 4.2-3 that "...a reduction in available water resources for irrigation" is an example of indirect impacts on agricultural land due to loss of topsoil from increased wind and water erosion.
But the County fails to analyze or propose mitigation measures to address this significant impact.

Ventura County Coalition of Labor, Agriculture and Business / 1672 Donlon Street, Ventura, CA
93003 / 805-633-2260 / info@colabvc.org

Page 4 of 4

APAC is the expert charged with advising County decision-makers on agricultural issues in Ventura County. And the County should be seeking guidance from APAC about the actual issues that will impact farmland under the 2040 General Plan: lack of economic sustainability, the increasing regulatory demands on agriculture, increased competition for water resources, and increased compatibility conflicts from development.

CoLAB encourages APAC to provide guidance to the County on appropriate and effective mitigation measures to prevent the conversion of agricultural land to non-agricultural uses. These may include:

- 1) Strengthen the Right-to-Farm ordinance to prevent nuisance complaints from being used to justify the creation or expansion of setbacks or regulatory restrictions on normal farming practices;
- 2) Expand the Land Conservation Act Program to include Open Space zoned properties that are engaged in farming (including grazing); and
- 3) Protect agricultural land from urban-ag interface encroachment and compatibility conflicts by establishing setbacks on NON-AE-zoned land that will restrict the construction of bike paths, public trails, and sensitive receptors within 2000' of any land zoned A/E.

Thank you again for the opportunity to provide comments on this issue. We appreciate your consideration and leadership at this time.

Sincerely,

Louise Lampara Executive Director

Subject: General Plan / EIR Comments

To: Susan Curtis-

County failed to evaluate mitigation measure for feasibility- 500' set back for "sensitive receptors" from freeways and high traffic roads.

Mitigation Measure AQ-3 (Policy HAZ10-X) creates a minimum 500' set back for "sensitive receptors" from freeways and high traffic roads. Yet the County states in the Land Use section of the EIR that "the majority of the anticipated build out will be within the freeway corridors."

Has the County completed a "buildout study" to ensure that the establishment of this set back still leaves enough room for development to occur? Will this mitigation measure be economically feasible?

1000 S. Seaward Avenue
Ventura, CA 93001

February 24, 2020

Ventura County Board of Supervisors
Attn: RMA Planning Division
General Plan Update
800 Victoria Avenue L#1740
Ventura, California 93009-1740

Dear Board of Supervisors and Staff:

We are writing this letter to urge the Board of Supervisors to reconsider moving forward with the Draft General Plan EIR. The draft EIR has been accelerated to the point that too many issues and impacts have not been properly addressed or studied. These impacts and the corresponding mitigation measures will have severe impacts to land owners and especially those, like us in the agricultural industry and other productive economic segments.

Our family has been involved in the agricultural industry for more than 100 years in Ventura County. We have owned numerous land holdings that remain in the family to this date. We have farmed throughout Ventura County and hope to continue to do so in the future.

The Draft EIR is deficient on many levels. CEQA requires that all mitigation measures must be technically and economically feasible. Numerous proposed mitigation measures are neither. We have in the past attempted to identify land and any owners that would be open to sell their development rights for land that was converting from agricultural to commercial use. Not only did we not find anyone that would do so, no one would even quote a price. The only positive response from numerous land owners were that you can buy my property for full market value and then you can do what you want. There is not a project that can be built by adding double land cost to the equation. This was very recently experienced based on proposed policies at LAFCo. These policies were eventually not enacted due to the inability to purchase development rights in an economical feasible manner. This was when LAFCo was contemplating an acre for acre ag preserve. The new policy that is proposed in the 2040 General Plan is requiring 2 acres for every 1 acre of land converted from ag to any other use. This will eliminate the ability to add any new required ag buildings or even farm worker housing. The Draft EIR must study these impacts, since they are not feasible.

The Draft EIR also deals with water in a manner that is not properly studied. There is no analysis on increased water costs and diminishing availability of water. Without reasonable water costs and supply, there is no agricultural industry.

The General Plan indicates that agriculture is a high priority in the County. However, new policies and requirements in the General Plan add additional mitigation measures that will make ag virtually impossible. These include new setbacks, limiting types of fumigants pesticides and fertilizers. The General Plan also requires the conversion of all farm equipment to be all electric. Again, not feasible. The costs to purchase new pumps, farm equipment and other existing fuel using equipment will increase operational costs to a point that the County crops will not be competitive in the open market. These new mitigation measures are not sufficiently studied and again are not economically feasible.

The Draft EIR is extremely difficult to read and understand. The background reports are lacking in depth of what has been studied other than numerous general statements and very poor mapping. Detailed studies must be added to sufficiently identify impacts and the related mitigation measures for both direct and indirect impacts on the agricultural industry. It is our understanding that reports and studies need to be timely prepared. However numerous studies are older than 5 years. Not timely.

After numerous devastating wildfires over the last few years, which significantly impacted ag, the General Plan continues to lay out limiting mitigation measures for fire prevention. The Wildlife corridor eliminates any ag operation or fire prevention in the proposed corridor areas. This is also a major concern not studied in the Draft EIR.

The Draft EIR for the 2040 General plan does not provide adequate analysis for the expansion of permanent bike paths and pedestrian walking trails throughout the County. These impacts are very severe due to constant conflicts from trail users and ag operations. Spraying, dust, odors from ag operations, along with impacts created by the trail users. These are usually theft, vandalism, litter and pet waste. The proposed mitigation measures require additional setbacks from these trails which renders additional land unusable for ag operations.

In addition to the above comments on the agricultural aspects and related land use concerns of the DEIR, the undersigned is also a mineral owner directly interested in the impacts on oil and gas production of the DEIR and related General Plan 2040 proposed provisions. In these documents there is a total failure to address the economic impacts of the various policies proposed in violation of the requirements for this process, including but not limited to the loss of royalty income to a large group of County residents. I join in the detailed comments on the various deficiencies and concerns identified in the DEIR as described in the concurrent submissions on behalf of Aera Energy and other operators delivered this week to the County.

Please look at the long-term consequences of these General Plan policies and mitigation measures. We formally request additional studies and a revised Draft EIR that will properly look at these and many more issues. The DEIR must be corrected with details of the revisions. Then it can be recirculated.

Sincerely,

Marianne McGrath

What about public safety

Attention: Health & Safety

Date: 02/27/2020

02/27/20 09:25:11

What about public safety?

When I built my house at 209 Heavenly Valley Rd, Newbury Park in 1994, it was considered a single-family dwelling. Now 32% of the people on Heavenly Valley Rd rent out their rooms.

If they are a couple they have at least two cars. The houses in our neighborhood range from three to six bedrooms, and when they convert the garage into another unit, they really have a problem with the parking.

My neighbor has a six bedroom house with a bonus room of about 800 square feet. He currently rents out rooms inside his home. He is in the process of converting his garage into a 1200 square foot, three bedroom apartment and an office. He has enough parking for five cars in the driveway. This will require additional parking, but where will this parking be? I don't know, and I don't know that the county knows. It seems the permit was handed out without anyone doing due diligence to find out this answer.

If you do the math, and they have six bedrooms, and a bonus room, add the three bedroom apartment, and the office, how much parking is needed? Everyone in California has a car, and all these cars will be on the street.

Four times in the last 2 1/2 years an ambulance and a firetruck have been stuck to where either they had to wheel the patient down the street or go around the block because the street was blocked off by the parked cars. Again, the streets in this area are only 20 feet wide, and it forces people to park their cars on the street because of over occupancy.

There is also another problem. The street is a gateway to the Santa Monica Mountains which in the past has always been a huge fire concern. Please look on the map and you'll see the gateway I am speaking about. Who says that emergency personnel will be able to get up the street or down the street once these changes are implemented?

Has anyone asked the county/city fire department if they have had issues getting up this street? I hope so, and that should go on record what they had to say. I don't know whether to say no parking on the street or provide more parking but something needs to happen. These homes were meant to be only single-family dwellings and you've converted them into an apartment with absolutely no parking and when I talk to the building department they come up with some nonsense that there's a bus stop within half a mile, which it is slightly over that and we don't need parking, really.

The occupancy has changed but the code has done nothing for the safety or for the provisions of the people living here. It is my understanding that fire sprinklers are not mandatory, and why aren't they?

I hope you think of the public safety before you consider anymore garages changed into units, the Community demands more integrity than you're giving us.

Subject: 2040 General Plan Draft EIR Comment

Ventura County Board of Supervisors

Attn: RMA Planning Division

General Plan Update

800 Victoria Avenue L#1740

Ventura, California 93009-1740

Dear Board of Supervisors and Staff:

My family has owned for generations and continues to own agricultural properties in Ventura County, including mineral rights under a number of currently and previously owned parcels. I'm writing to you as an owner of mineral rights in Ventura County.

The 2040 General Plan Draft EIR fails to give proper analysis to mineral resources and must be corrected to more adequately and fairly assess the impact of the proposed general plan on owners of mineral rights.

Neither the EIR nor the Background Report provide a complete and thorough description of the existing regulations affecting the management and production of mineral resources in the County and the State of California. The EIR and the Background Report only disclose federal and state agencies that regulate pipelines and flaring, which is not applicable to all mineral resources that must be analyzed in an EIR under CEQA guidelines. The EIR should be revised to include an overview and description of all potential regulations, regulatory bodies, and programs that regulate mineral resources in Ventura County.

The EIR fails to analyze the direct and indirect impacts to mineral resource development as a result of the 2040 General Plan. The County admits that Land Use Designation changes in the 2040 General Plan will result in changes to land uses over known and important mineral reserves. But neither the EIR nor the Background Report provide any information regarding the anticipated "buildout" in terms of acreage, actual location, number of dwelling units, and development density and intensity.

As incompatible land uses (such as residential development) occur on or adjacent to mineral production and mineral reserves, compatibility conflicts will increase. Reasonably foreseeable indirect impacts include nuisance complaints, traffic conflicts, theft, vandalism and attempted trespass on mineral production sites. The EIR must analyze and evaluate these impacts on the ability to develop and manage mineral resources in the County.

Gaps in the 2040 General Plan Draft EIR must be corrected, and the Draft EIR recirculated, to fairly present the foreseeable impacts on owners of mineral rights in the County.

Sincerely,

Marshall C. Milligan

Ventura County Board of Supervisors
Attn: RMA Planning Division
General Plan Update
800 Victoria Avenue L#1740
Ventura, California 93009-1740

Dear Board of Supervisors and Staff:

We are writing this letter to urge the Board of Supervisors to reconsider moving forward with the Draft General Plan EIR. The draft EIR has been accelerated to the point that too many issues and impacts have not been properly addressed or studied. These impacts and the corresponding mitigation measures will have severe impacts to land owners and especially those, like us in the agricultural industry and other productive economic segments.

Our family has been involved in the agricultural industry for more than 100 years in Ventura County. We have owned numerous land holdings that remain in the family to this date. We have farmed throughout Ventura County and hope to continue to do so in the future.

The Draft EIR is deficient on many levels. CEQA requires that all mitigation measures must be technically and economically feasible. Numerous proposed mitigation measures are neither. We have in the past attempted to identify land and any owners that would be open to sell their development rights for land that was converting from agricultural to commercial use. Not only did we not find anyone that would do so, no one would even quote a price. The only positive response from numerous land owners were that you can buy my property for full market value and then you can do what you want. There is not a project that can be built by adding double land cost to the equation. This was very recently experienced based on proposed policies at LAFCo. These policies were eventually not enacted due to the inability to purchase development rights in an economical feasible manner. This was when LAFCo was contemplating an acre for acre ag preserve. The new policy that is proposed in the 2040 General Plan is requiring 2 acres for every 1 acre of land converted from ag to any other use. This will eliminate the ability to add any new required ag buildings or even farm worker housing. The Draft EIR must study these impacts, since they are not feasible.

The Draft EIR also deals with water in a manner that is not properly studied. There is no analysis on increased water costs and diminishing availability of water. Without reasonable water costs and supply, there is no agricultural industry.

The General Plan indicates that agriculture is a high priority in the County. However, new policies and requirements in the General Plan add additional mitigation measures that will make ag virtually

impossible. These include new setbacks, limiting types of fumigants pesticides and fertilizers. The General Plan also requires the conversion of all farm equipment to be all electric. Again, not feasible. The costs to purchase new pumps, farm equipment and other existing fuel using equipment will increase operational costs to a point that the County crops will not be competitive in the open market. These new mitigation measures are not sufficiently studied and again are not economically feasible.

The Draft EIR is extremely difficult to read and understand. The background reports are lacking in depth of what has been studied other than numerous general statements and very poor mapping. Detailed studies must be added to sufficiently identify impacts and the related mitigation measures for both direct and indirect impacts on the agricultural industry. It is our understanding that reports and studies need to be timely prepared. However numerous studies are older than 5 years. Not timely.

After numerous devastating wildfires over the last few years, which significantly impacted ag, the General Plan continues to lay out limiting mitigation measures for fire prevention. The Wildlife corridor eliminates any ag operation or fire prevention in the proposed corridor areas. This is also a major concern not studied in the Draft EIR.

The Draft EIR for the 2040 General plan does not provide adequate analysis for the expansion of permanent bike paths and pedestrian walking trails throughout the County. These impacts are very severe due to constant conflicts from trail users and ag operations. Spraying, dust, odors from ag operations, along with impacts created by the trail users. These are usually theft, vandalism, litter and pet waste. The proposed mitigation measures require additional setbacks from these trails which renders additional land unusable for ag operations.

In addition to the above comments on the agricultural aspects and related land use concerns of the DEIR, the undersigned is also a mineral owner directly interested in the impacts on oil and gas production of the DEIR and related General Plan 2040 proposed provisions. In these documents there is a total failure to address the economic impacts of the various policies proposed in violation of the requirements for this process, including but not limited to the loss of royalty income to a large group of County residents. I join in the detailed comments on the various deficiencies and concerns identified in the DEIR as described in the concurrent submissions on behalf of Aera Energy and other operators delivered this week to the County.

Please look at the long-term consequences of these General Plan policies and mitigation measures. We formally request additional studies and a revised Draft EIR that will properly look at these and many more issues. The DEIR must be corrected with details of the revisions. Then it can be recirculated.

Sincerely,

Gregory H. Smith

Subject: Ventura County Board of Supervisors , Petition to VC Supervisors and Planners about VC2040 Draft General Plan and EIR

CAUTION: If this email looks suspicious, DO NOT click. Forward to Spam.Manager@ventura.org

Ventura County Board of Supervisors ,

206 people have signed a petition on Action Network telling you to Petition to VC Supervisors and Planners about VC2040 Draft General Plan and EIR.

Here is the petition they signed:

With worsening climate change impacts, we reiterate and amplify the concerns the people expressed in January of last year about “climate change

and GHGs, and the effects of continued oil and gas extraction including secondary effects related to climate change, air quality, water quality, water supply, traffic, noise, odors, aesthetics, and hazards.”

Our county is warming faster than any other in the nation, our ocean is becoming more hostile to marine life, our last drought was the most intense and lasted longest, and our history of costly floods will be dwarfed when future atmospheric rivers pour over our valleys. Our house is on fire. We need a thorough plan and environmental impacts analysis based on the latest science.

Ventura County’s plan matters. Our larger cities are making climate action plans and look for your example of leadership. The environmental impact from what we do to mitigate climate impacts at the global scale is profoundly influential in trying to stop runaway climate change. This is explained in a new report Insights from the California Energy Policy Simulator about the role of the State of California in the world. Ventura County as a local government hit hardest by climate impacts must step up and meet serious goals. “Insights about California’s climate policies are at the forefront of global efforts to battle climate change. The state’s leadership and success so far have helped maintain momentum despite political headwinds. If California faltered, global efforts to reduce GHG emissions would be dealt a major setback. Meanwhile, the severe risks from runaway global warming are becoming more tangible as the state suffers from wildfires supercharged by climate change.”

A. Four Overall Comments:

We are grateful for the expertise at the law firm of Shute, Mihaly and Wineberger retained by CFROG regarding CEQA. We have appreciated their past comments. We join them in continuing to request the following:

1. Count ALL GHGs that result from activity in our county: Count all burning of oil and gas originating in our county and count all fugitive methane from wells in our county and from methane entering our county that was not counted at the jurisdiction of origin. Do the math on the GHG footprint for heavy exports. We want to mitigate our fair share of all climate impacts from activities within Ventura County. We have to know what they are. Worrying about double

counting is not acceptable. Just worry that you haven't counted every cause of climate impacts that we are morally and legally responsible to mitigate with a comprehensive inventory and a systematic plan.

2. Use the latest science to calculate GWP of methane: The global warming potential of GWP is nearly 40 percent greater than what you are using. The International Panel on Climate Change states that over a 20 year period, methane has a GWP of 84 compared to carbon dioxide (up from their previous estimate of 72). The US EPA estimates it at 87 and recent scientific experts put the estimate at 96. We must know the true environmental impact of methane emissions. A complete and scientifically valid GHG inventory is required for a CEQA-compliant Climate Action Plan.

3. Use the emissions reduction goal from Governor Brown's Executive Order B-18-55 "to achieve carbon neutrality as soon as possible, and no later than 2045, and achieve and maintain net negative emissions thereafter. This goal is in addition to the existing statewide targets of reducing greenhouse gas emissions." It is an inadequate compromise, but not as much as the SB 32 goal of 80% below 1990 levels by 2050. City of LA plans to stay within a net zero carbon budget between now and 2045. The proposed GHG reductions in the VC2040 Draft of 41 percent below 2015 levels by 2030, 61 percent by 2040, and 80 percent by 2050 are not ambitious enough for us to do our part to mitigate the climate chaos happening faster than scientists have predicted.

4. Policies and programs must meet the goal: It does not take an in-depth analysis to see that this plan will not achieve the 2030 goal of 40% reduction in GHGs below 1990 levels. A new report Insights from the California Energy Policy Simulator shows that the State of California will fall short of that goal by at least 15 and as much as 45 MMT CO₂e. We have and continue to advocate for a goal aligned with Governor Brown's Executive Order to achieve carbon neutrality as soon as possible and no later than 2045.

B. Some Comments about Impacts and Mitigation

The environmental impacts that concern us are those resulting from governments not making and carrying out plans to mitigate climate change. Your draft analysis does not include most of them. Table B in the Executive

Summary is not even half finished. Some of the more serious impacts are missing from the draft analysis. Here are a few of our concerns:

1. Aesthetics, Scenic Resources and Light Pollution and Agriculture and Forest Resources: Mitigation programs are needed to protect our resources from degradation from significant climate impacts. The loss of soil in particular is associated with the downfall of civilizations.

2. Air Quality: The emissions impacts from exceeding criteria pollutant thresholds and also greenhouse gases seem significant and can be mitigated.

3. Biological Resources: The new implementation program is a good start to “update the Initial Study Assessment Guidelines, Biological Resources Assessment report criteria and evaluate discretionary development that could potentially impact sensitive biological resources”. Two kinds of impacts are missing. 1) Climate Change. A major mitigation is the restoration of wetlands which should be at a 2:1 or greater ratio. Stormwater management is another mitigation that reverses the loss of vegetation from drought and floods and supports the restoration of all of the indigenous biology that makes an ecosystem function to maintain the small water cycles. 2) Toxic Pesticide and Herbicide Use and Drift. This must be part of the agenda of a Program for Protection of Sensitive Biological Resources to promulgate the mitigations provided by Integrated Pest Management. Pest management policy must align with the recommendations of the California Department of Pesticide Regulation Roadmap for Integrated Pest Management some of which have climate mitigation co-benefits.

4. Energy: We want a workshop to learn how it is deemed less than significant to allow wasteful, inefficient, or unnecessary consumption of energy resources.

5. Greenhouse Gas Emissions: The climate change impacts are so dire that the mitigations need to be benchmarked to be achieved before it is too late to reverse runaway climate chaos. At minimum we demand a systematic plan for decarbonization of county facilities and electrification of the transportation system.

6. Hazards, Hazardous Materials, and Wildfire: The impacts of toxic explosions, leaks, and spills and the drift of regulated materials and the ignorance of the public about toxic impacts must be addressed where feasible through mitigations that regulate the use and transport of hazardous materials. We have recommended feasible mitigations for people being exposed to the risk of wildfires that have not been accepted by decision-makers.

7. Hydrology and Water Quality: Impacts from climate change and poor land management have have led to grave threats to water supply and water quality. These are highly significant--ground water overdraft, overuse and degradation of water quality, erosion, flooding, and siltation. (Impact 4.10-12) The failure to restore small water cycles to keep stormwater in the uplands and maintain forest health is one of the most serious impacts being mitigated in many places through a paradigm shift about stormwater management. Mitigation is essential--water is life. It requires an integrated water management plan that involves every sector working on every mitigation of which we are aware.

8. Land Use and Planning We want an analysis of incompatible land uses and new development with negative health implications. Closing wells near sensitive sites is a mitigation. Environmental Justice is not examined in the draft EIR.

9. Mineral and Petroleum Resources: We want an analysis of the impact of the scenario in which wells have been put on hold and the operator cannot close the wells for lack of funds. We have no choice. The wells must be closed properly. Fields must be restored to functioning ecosystems to help mitigate climate change impacts. We need insurance as well as bigger bonds.

10. Traffic and Transportation: Tailpipe emissions is an extremely significant environmental impact. The mitigation aimed for in the CTM-C: Vehicle Miles Traveled (VMT) Reduction Program needs assurances of effectiveness via a clear description of what "conditions warrant providing additional mitigations and programs"? This is far too vague to be a mitigation for this significant

impact. We have no alternative but to reliably cut GHGs in the transportation sector.

11. Utilities: Failure to develop wholesale and commercial scale renewable energy generation and microgrids is a significant environmental impact because it has forced us to have to get our electricity from fossil fuels via transmission lines that spark wildfires. Community microgrids are a feasible mitigation.

12. Waste Management: Failure to properly manage waste has a highly significant environmental impact, especially when it produces methane super-emitter landfills that is driving climate change, but also the failure to reuse and recycle consumer goods and the materials and equipment discarded by commercial enterprises. We need a more comprehensive approach for mitigation of these impacts.

C. The following policy recommendations for the Draft Plan could help the Plan achieve the GHG reduction goals to mitigate climate change impacts and help the EIR be more relevant to the climate crisis.

Land Use and Community Character: We endorse the comments submitted by Bruce Smith to more firmly assure preservation of agricultural land and open space. We point out the lack of analysis of Environmental Justice policy issues.

Circulation, Transportation, and Mobility:

1. No overriding considerations should allow a project to NOT reduce VMT unless all of the vehicles have zero emissions that will use the proposed project.
2. CTM 3-9 to widen SR 118 has a significant environmental impact.
3. Benchmarks to reduce VMT need to be more clear and the plan needs a review with public input every two years until 2028 and then no longer than every five years.
4. Parking programs should be included in ways that reduce single-occupancy car trips.

Public Facilities, Services, and Infrastructure:

1. Enroll residents in a program to reduce CO2 emissions in their neighborhoods. Ex: Cool Block or Transition Streets.
2. PFS 2.1 must be revised to say include rather than encourage 'Sustainable Plans and Operations' in order to be considered a mitigation of climate change impacts from greenhouse gas emissions.
3. Policy PFS 7.1 should be revised to delete the need for access to gas. The environmental impact from use of natural gas requires carbonizing buildings beginning with no gas connections to new residences . It is therefore contradictory to ensure access to gas.
4. Local renewable energy generation must be part of the mitigation plan for reducing transmission facility fire hazard risk. This is not the same as "Smart Grid Technology". You need experts who know the cutting edge of this field to help write coherent policy on this topic.
5. Zero Waste The County shall achieve zero waste (via a suite of policies to reduce, reuse, and recycle) with no organic waste going to landfills by 2023
6. Zero Waste Policy for Meetings and Events Design and implement a zero waste policy for meetings and events sponsored or permitted by the County to minimize waste and rescue surplus edible food
7. Compostable Take-Out Foodware Require that take-out foodware be made with material compostable in solid waste processing facilities within 60 days
8. Reduce Solid Waste by Phasing Out Single-Use Plastic Evaluate how to best reduce solid waste generation per capita by at least 15% by 2030 including phasing out single-use plastics including but not limited to plastic straws, plastic utensils, plastic take-out containers, and expanded polystyrene
9. Ban Expanded Polystyrene

Conservation and Open Space:

1. Reduce oil and gas production by 40% by 2025 via higher monitoring standards and 2500 ft buffer zones near sensitive sites; reduce production to zero by no later than 2040.
2. Phase-Out of Oil and Gas Production The County shall prohibit new drilling and shall regulate existing wells to assure steady closing of wells beginning near residential and commercial areas.
3. Maintain Policy COS-7.8 as recommended by the Board of Supervisors, so that all newly permitted discretionary oil wells are required to collect gases

and use or remove them for sale or proper disposal instead of flaring or venting. Flaring should be allowed only in cases of emergency or for testing purposes.

4. Maintain Policy COS-7.7 as recommended by the Board of Supervisors, so that all newly permitted discretionary oil wells are required to convey oil and produced water via pipelines instead of trucking.

5. Detect and curb methane emissions from “super-emitter” sites as identified by NASA.

6. Tax oil and gas production, and related uncaptured methane to raise the needed revenues to fund urgent climate programs to replace high-emission vehicles with a priority on trucking and freight companies, fishing businesses, general contractors and K-12 schools.

7. Require a fully accountable performance bond for all new wells to cover cost of closure Cite LAT article (maybe put on website and link to it).

8. Establish an insurance fund that oil and gas producers contribute to that will cover accidents and closing wells if the producer goes bankrupt.

9. Ban gas-fueled lawn and garden equipment. (Ex: City of Ojai)

10. Accelerate capture of legacy HFCs Enlist the public and private to find and destroy existing stocks of HFC’s (refrigerant gases with extremely high Global Warming Potential).

11. Develop and adopt building codes based on best practices for use of low embodied carbon concrete and set targets for use of low GHG concrete alternatives. Ex: Bay Area Air Quality Management District and King Co, WA.

12. Encourage climate-safe and climate-resilient development through zoning reform and removal of limits on height, density, and minimum parking requirements to enable and promote walkability and a mix of uses for homes and businesses, parks and transit.

13. Create a master local clean energy siting and funding plan for wholesale distributed solar energy plus storage in commercial scale projects producing energy needs by 2030.

14. Provide energy efficiency benchmarking and rebates for low-income housing and renters as well as low-interest loans for small businesses to reduce energy use; assist owners of existing buildings to switch from natural gas to electricity.

15. Prepare sustainable building, siting, landscaping and passive heating and cooling practice guidelines, with a priority on low-income housing, that reduce

consumption of non-renewable resources and that include climate and fire-safety in pre-approved plans.

16. Energy Efficiency to Reduce Electricity Use Use Energy Efficiency to Deliver 15% of Projected Needs for electricity in the county by 2023; and 30% by 2030.

17. Efficiency Building Standards for Retrofits Prioritize energy and water efficiency building standards and work to retrofit existing buildings.

18. Decarbonize County Buildings Develop a county building electrification plan eliminating natural gas use in County-owned facilities.

19. Decarbonize All Building Types Develop an electrification plan with goals for GHG emission reductions through renewable energy that evaluates and prioritizes programs for local solar, energy storage and demand response (DR) that disconnects all buildings from gas service by 2050. Include incentives for deep retrofits of inefficient buildings.

Agriculture:

1. Integrated Pest Management where toxic pesticides are a last resort.

Create a program that promotes the principles (systems approach, building trust, and effective communication) and pursues the recommendations of the Roadmap for Integrated Pest Management from the University of California and CA Department of Pesticide Regulation. Environmental impacts from toxic pesticides are not described in the Background Report. The Roadmap to an Organic California Policy Report by CCOF Foundation offers information for mitigations and climate action. A workshop is needed.

2. Inorganic Nitrogen Based Fertilizers Set benchmarks for reducing use of inorganic N fertilizer and encourage optimized use of organic and inorganic fertilizer for greatest efficiency in closed nutrient cycles, monitor for nutrient runoff from fields and encourage the use of cover crops and green manure crops to reduce or avoid nitrous oxide (N₂O) emissions and nutrient runoff.

3. Diversified Cropping Systems Encourage farmers to include 1 – 5% of beneficial insect attracting plants in a planted crop, and other methods, such as crop rotation, perennial mowed cover crop in orchards, and integrating multiple species or varieties to enhance the biological and economic stability by spreading economic risk and buffering against pest invasions and extreme weather events, and increase carbon sequestration.

4. Reward Regenerative Farmers with Digestate and Compost from Food

Waste Research feasibility of a program for composting food waste for use by farmers and landscapers who use regenerative practices that sequester certified amounts of CO₂.

Water Resources:

1. At least 30,000 acre-feet per year must come from storm water capture by 2035
2. All rainfall must be retained onsite in soil and reservoirs.
3. Slow It. Spread It. Sink It! The County shall enforce Best Management Practices (BMP) and Low Impact Development (LID) for new developments.
4. Recycle all wastewater for beneficial reuse by 2035.
5. Reduce potable water use per capita by 22% by 2025 and 25% by 2035: Offer incentives for water conservation features, including drought tolerant landscaping, permeable materials in standard parkway design guidelines, street trees, infiltration, greywater, and water-saving plumbing.
6. Close oil and gas wells and injection wells near aquifers as a top priority.
7. Create a Master Plan to develop the full potential of integrated water management to infiltrate the ground and recharge aquifers; support reforestation and restoration of watershed ecosystems; conserve and protect groundwater resources, and clean up creeks, streams, and estuaries.
8. Support Santa Clara River Loop Trail and Ventura River Trail Development

Economic Vitality:

1. Agricultural Diversification should include reference to regenerative practices to create biodiversity with opportunities for community members to visit farms.
2. Small Business Promotion. Support approval of caretaker residential space on business property to reduce VMT and more financial strength for small businesses.
3. Green Economy. Prioritize youth and immigrants for workforce development in industries that promote and enhance environmental sustainability, including GHG reductions, climate adaptation, resiliency and local renewable energy generation, storage and distribution, including solar power, wind power, wave energy, regenerative organic farming and value-added agriculture-related activities, and other appropriate renewable sources.
4. Maritime Economy. Facilitate a sustainable maritime economy using

restorative aquaculture techniques that restore ocean health and biodiversity while reviving pre-human fisheries abundance. For example, restore sand-bottom kelp forests and increase kelp forests with flexible floating fishing reefs where the seafloor is otherwise too deep for kelp.

5. Promote Fire-Resistant Infill and Revitalization. Encourage infill development that serves as firebreak rather than as additional fuel for wildfires.

6. Create a Collaborative Structure for Innovation for a Resilient Future. The structure should be able to make decisions and create a way forward for zoning, building and materials and environmental health to allow options for a resilient future, include government officials, innovators and public as described in submissions from Sustainable Living Research Initiative.

7. Parking Infrastructure. Develop parking policies to reduce single occupancy trips associated with employees and business activity to reduce Vehicle Miles Traveled.

8. Master Plan for Distributed Energy Resources and Community Microgrids. Prepare a map of siting options for renewable energy generation and storage facilities and coordinate the identification of financing options for renewable energy resource development, including solar, wind, wave, storage and community microgrids both in front of and behind the meter.

In summary, with the accelerating tipping points, we cannot go half-way in our vision. We need extraordinary courage to set goals we can hang our hopes and efforts on. We want completeness and clarity so we can see how the emissions reduction plan adds up. We want respect for climate science to tell us the truth. We want more ambition. A 2016 decision of the state legislature in SB32 is just not good enough as a goal. We want to see a systematic plan that will assure carbon neutrality no later than 2045.

You can view each petition signer and the comments they left you in the attached PDF.

Thank you,

Christopher Tull

Ventura County Board of Supervisors ,

206 people have signed a petition on Action Network telling you to Petition to VC Supervisors and Planners about VC2040 Draft General Plan and EIR.

Here is the petition they signed:

With worsening climate change impacts, we reiterate and amplify the concerns the people expressed in January of last year about “climate change and GHGs, and the effects of continued oil and gas extraction including secondary effects related to climate change, air quality, water quality, water supply, traffic, noise, odors, aesthetics, and hazards.”

Our county is warming faster than any other in the nation, our ocean is becoming more hostile to marine life, our last drought was the most intense and lasted longest, and our history of costly floods will be dwarfed when future atmospheric rivers pour over our valleys. Our house is on fire. We need a thorough plan and environmental impacts analysis based on the latest science.

Ventura County’s plan matters. Our larger cities are making climate action plans and look for your example of leadership. The environmental impact from what we do to mitigate climate impacts at the global scale is profoundly influential in trying to stop runaway climate change. This is explained in a new report Insights from the California Energy Policy Simulator about the role of the State of California in the world. Ventura County as a local government hit hardest by climate impacts must step up and meet serious goals. “Insights about California’s climate policies are at the forefront of global efforts to battle climate change. The state’s leadership and success so far have helped maintain momentum despite political headwinds. If California faltered, global efforts to reduce GHG emissions would be dealt a major setback. Meanwhile, the severe risks from runaway global warming are becoming more tangible as the state suffers from wildfires supercharged by climate change.”

A. Four Overall Comments:

We are grateful for the expertise at the law firm of Shute, Mihaly and Wineberger retained by CFROG regarding CEQA. We have appreciated their past comments. We join them in continuing to request the following:

1. Count ALL GHGs that result from activity in our county: Count all burning of oil and gas originating in our county and count all fugitive methane from wells in our county and from methane entering our county that was not counted at the jurisdiction of origin. Do the math on the GHG footprint for heavy exports. We want to mitigate our fair share of all climate impacts from activities within Ventura County. We have to know what they are. Worrying about double counting is not acceptable. Just worry that you haven’t counted every cause of climate impacts that we are morally and legally responsible to mitigate with a comprehensive inventory and a systematic plan.

2. Use the latest science to calculate GWP of methane: The global warming potential of GWP is nearly 40 percent greater than what you are using. The International Panel on Climate Change states that over a 20 year period, methane has a GWP of 84 compared to carbon dioxide (up from their previous estimate of 72). The US EPA estimates it at 87 and recent scientific experts put the estimate at 96. We must know the true environmental impact of

methane emissions. A complete and scientifically valid GHG inventory is required for a CEQA-compliant Climate Action Plan.

3. Use the emissions reduction goal from Governor Brown's Executive Order B-18-55 "to achieve carbon neutrality as soon as possible, and no later than 2045, and achieve and maintain net negative emissions thereafter. This goal is in addition to the existing statewide targets of reducing greenhouse gas emissions." It is an inadequate compromise, but not as much as the SB 32 goal of 80% below 1990 levels by 2050. City of LA plans to stay within a net zero carbon budget between now and 2045. The proposed GHG reductions in the VC2040 Draft of 41 percent below 2015 levels by 2030, 61 percent by 2040, and 80 percent by 2050 are not ambitious enough for us to do our part to mitigate the climate chaos happening faster than scientists have predicted.

4. Policies and programs must meet the goal: It does not take an in-depth analysis to see that this plan will not achieve the 2030 goal of 40% reduction in GHGs below 1990 levels. A new report Insights from the California Energy Policy Simulator shows that the State of California will fall short of that goal by at least 15 and as much as 45 MMT CO₂e. We have and continue to advocate for a goal aligned with Governor Brown's Executive Order to achieve carbon neutrality as soon as possible and no later than 2045.

B. Some Comments about Impacts and Mitigation

The environmental impacts that concern us are those resulting from governments not making and carrying out plans to mitigate climate change. Your draft analysis does not include most of them. Table B in the Executive Summary is not even half finished. Some of the more serious impacts are missing from the draft analysis. Here are a few of our concerns:

1. Aesthetics, Scenic Resources and Light Pollution and Agriculture and Forest Resources: Mitigation programs are needed to protect our resources from degradation from significant climate impacts. The loss of soil in particular is associated with the downfall of civilizations.

2. Air Quality: The emissions impacts from exceeding criteria pollutant thresholds and also greenhouse gases seem significant and can be mitigated.

3. Biological Resources: The new implementation program is a good start to "update the Initial Study Assessment Guidelines, Biological Resources Assessment report criteria and evaluate discretionary development that could potentially impact sensitive biological resources". Two kinds of impacts are missing. 1) Climate Change. A major mitigation is the restoration of wetlands which should be at a 2:1 or greater ratio. Stormwater management is another mitigation that reverses the loss of vegetation from drought and floods and supports the restoration of all of the indigenous biology that makes an ecosystem function to maintain the small water cycles. 2) Toxic Pesticide and Herbicide Use and Drift. This must be part of the agenda of a Program for Protection of Sensitive Biological Resources to promulgate the mitigations provided by Integrated Pest Management. Pest management policy must align with the recommendations of the California Department of Pesticide Regulation Roadmap for Integrated Pest Management some of which have climate mitigation co-benefits.

4. Energy: We want a workshop to learn how it is deemed less than significant to allow wasteful, inefficient, or unnecessary consumption of energy resources.

5. Greenhouse Gas Emissions: The climate change impacts are so dire that the mitigations need to be benchmarked to be achieved before it is too late to reverse runaway climate chaos.

At minimum we demand a systematic plan for decarbonization of county facilities and electrification of the transportation system.

6. Hazards, Hazardous Materials, and Wildfire: The impacts of toxic explosions, leaks, and spills and the drift of regulated materials and the ignorance of the public about toxic impacts must be addressed where feasible through mitigations that regulate the use and transport of hazardous materials. We have recommended feasible mitigations for people being exposed to the risk of wildfires that have not been accepted by decision-makers.

7. Hydrology and Water Quality: Impacts from climate change and poor land management have led to grave threats to water supply and water quality. These are highly significant--ground water overdraft, overuse and degradation of water quality, erosion, flooding, and siltation. (Impact 4.10-12) The failure to restore small water cycles to keep stormwater in the uplands and maintain forest health is one of the most serious impacts being mitigated in many places through a paradigm shift about stormwater management. Mitigation is essential--water is life. It requires an integrated water management plan that involves every sector working on every mitigation of which we are aware.

8. Land Use and Planning We want an analysis of incompatible land uses and new development with negative health implications. Closing wells near sensitive sites is a mitigation. Environmental Justice is not examined in the draft EIR.

9. Mineral and Petroleum Resources: We want an analysis of the impact of the scenario in which wells have been put on hold and the operator cannot close the wells for lack of funds. We have no choice. The wells must be closed properly. Fields must be restored to functioning ecosystems to help mitigate climate change impacts. We need insurance as well as bigger bonds.

10. Traffic and Transportation: Tailpipe emissions is an extremely significant environmental impact. The mitigation aimed for in the CTM-C: Vehicle Miles Traveled (VMT) Reduction Program needs assurances of effectiveness via a clear description of what "conditions warrant providing additional mitigations and programs"? This is far too vague to be a mitigation for this significant impact. We have no alternative but to reliably cut GHGs in the transportation sector.

11. Utilities: Failure to develop wholesale and commercial scale renewable energy generation and microgrids is a significant environmental impact because it has forced us to have to get our electricity from fossil fuels via transmission lines that spark wildfires. Community microgrids are a feasible mitigation.

12. Waste Management: Failure to properly manage waste has a highly significant environmental impact, especially when it produces methane super-emitter landfills that is driving climate change, but also the failure to reuse and recycle consumer goods and the materials and equipment discarded by commercial enterprises. We need a more comprehensive approach for mitigation of these impacts.

C. The following policy recommendations for the Draft Plan could help the Plan achieve the GHG reduction goals to mitigate climate change impacts and help the EIR be more relevant to the climate crisis.

Land Use and Community Character: We endorse the comments submitted by Bruce Smith to more firmly assure preservation of agricultural land and open space. We point out the lack of analysis of Environmental Justice policy issues.

Circulation, Transportation, and Mobility:

1. No overriding considerations should allow a project to NOT reduce VMT unless all of the vehicles have zero emissions that will use the proposed project.
2. CTM 3-9 to widen SR 118 has a significant environmental impact.
3. Benchmarks to reduce VMT need to be more clear and the plan needs a review with public input every two years until 2028 and then no longer than every five years.
4. Parking programs should be included in ways that reduce single-occupancy car trips.

Public Facilities, Services, and Infrastructure:

1. Enroll residents in a program to reduce CO2 emissions in their neighborhoods. Ex: Cool Block or Transition Streets.
2. PFS 2.1 must be revised to say include rather than encourage 'Sustainable Plans and Operations' in order to be considered a mitigation of climate change impacts from greenhouse gas emissions.
3. Policy PFS 7.1 should be revised to delete the need for access to gas. The environmental impact from use of natural gas requires carbonizing buildings beginning with no gas connections to new residences . It is therefore contradictory to ensure access to gas.
4. Local renewable energy generation must be part of the mitigation plan for reducing transmission facility fire hazard risk. This is not the same as "Smart Grid Technology". You need experts who know the cutting edge of this field to help write coherent policy on this topic.
5. Zero Waste The County shall achieve zero waste (via a suite of policies to reduce, reuse, and recycle) with no organic waste going to landfills by 2023
6. Zero Waste Policy for Meetings and Events Design and implement a zero waste policy for meetings and events sponsored or permitted by the County to minimize waste and rescue surplus edible food
7. Compostable Take-Out Foodware Require that take-out foodware be made with material compostable in solid waste processing facilities within 60 days
8. Reduce Solid Waste by Phasing Out Single-Use Plastic Evaluate how to best reduce solid waste generation per capita by at least 15% by 2030 including phasing out single-use plastics including but not limited to plastic straws, plastic utensils, plastic take-out containers, and expanded polystyrene
9. Ban Expanded Polystyrene

Conservation and Open Space:

1. Reduce oil and gas production by 40% by 2025 via higher monitoring standards and 2500 ft buffer zones near sensitive sites; reduce production to zero by no later than 2040.
2. Phase-Out of Oil and Gas Production The County shall prohibit new drilling and shall regulate existing wells to assure steady closing of wells beginning near residential and commercial areas.
3. Maintain Policy COS-7.8 as recommended by the Board of Supervisors, so that all newly permitted discretionary oil wells are required to collect gases and use or remove them for sale or proper disposal instead of flaring or venting. Flaring should be allowed only in cases of emergency or for testing purposes.
4. Maintain Policy COS-7.7 as recommended by the Board of Supervisors, so that all newly permitted discretionary oil wells are required to convey oil and produced water via pipelines instead of trucking.
5. Detect and curb methane emissions from "super-emitter" sites as identified by NASA.
6. Tax oil and gas production, and related uncaptured methane to raise the needed revenues to fund urgent climate programs to replace high-emission vehicles with a priority on trucking and freight companies, fishing businesses, general contractors and K-12 schools.
7. Require a fully accountable performance bond for all new wells to cover cost of closure Cite

LAT article (maybe put on website and link to it).

8. Establish an insurance fund that oil and gas producers contribute to that will cover accidents and closing wells if the producer goes bankrupt.
9. Ban gas-fueled lawn and garden equipment. (Ex: City of Ojai)
10. Accelerate capture of legacy HFCs Enlist the public and private to find and destroy existing stocks of HFC's (refrigerant gases with extremely high Global Warming Potential).
11. Develop and adopt building codes based on best practices for use of low embodied carbon concrete and set targets for use of low GHG concrete alternatives. Ex: Bay Area Air Quality Management District and King Co, WA.
12. Encourage climate-safe and climate-resilient development through zoning reform and removal of limits on height, density, and minimum parking requirements to enable and promote walkability and a mix of uses for homes and businesses, parks and transit.
13. Create a master local clean energy siting and funding plan for wholesale distributed solar energy plus storage in commercial scale projects producing energy needs by 2030.
14. Provide energy efficiency benchmarking and rebates for low-income housing and renters as well as low-interest loans for small businesses to reduce energy use; assist owners of existing buildings to switch from natural gas to electricity.
15. Prepare sustainable building, siting, landscaping and passive heating and cooling practice guidelines, with a priority on low-income housing, that reduce consumption of non-renewable resources and that include climate and fire-safety in pre-approved plans.
16. Energy Efficiency to Reduce Electricity Use Use Energy Efficiency to Deliver 15% of Projected Needs for electricity in the county by 2023; and 30% by 2030.
17. Efficiency Building Standards for Retrofits Prioritize energy and water efficiency building standards and work to retrofit existing buildings.
18. Decarbonize County Buildings Develop a county building electrification plan eliminating natural gas use in County-owned facilities.
19. Decarbonize All Building Types Develop an electrification plan with goals for GHG emission reductions through renewable energy that evaluates and prioritizes programs for local solar, energy storage and demand response (DR) that disconnects all buildings from gas service by 2050. Include incentives for deep retrofits of inefficient buildings.

Agriculture:

1. Integrated Pest Management where toxic pesticides are a last resort. Create a program that promotes the principles (systems approach, building trust, and effective communication) and pursues the recommendations of the Roadmap for Integrated Pest Management from the University of California and CA Department of Pesticide Regulation. Environmental impacts from toxic pesticides are not described in the Background Report. The Roadmap to an Organic California Policy Report by CCOF Foundation offers information for mitigations and climate action. A workshop is needed.
2. Inorganic Nitrogen Based Fertilizers Set benchmarks for reducing use of inorganic N fertilizer and encourage optimized use of organic and inorganic fertilizer for greatest efficiency in closed nutrient cycles, monitor for nutrient runoff from fields and encourage the use of cover crops and green manure crops to reduce or avoid nitrous oxide (N₂O) emissions and nutrient runoff.
3. Diversified Cropping Systems Encourage farmers to include 1 – 5% of beneficial insect attracting plants in a planted crop, and other methods, such as crop rotation, perennial mowed cover crop in orchards, and integrating multiple species or varieties to enhance the biological and economic stability by spreading economic risk and buffering against pest invasions and extreme weather events, and increase carbon sequestration.
4. Reward Regenerative Farmers with Digestate and Compost from Food Waste Research feasibility of a program for composting food waste for use by farmers and landscapers who use regenerative practices that sequester certified amounts of CO₂.

Water Resources:

1. At least 30,000 acre-feet per year must come from storm water capture by 2035
2. All rainfall must be retained onsite in soil and reservoirs.
3. Slow It. Spread It. Sink It! The County shall enforce Best Management Practices (BMP) and Low Impact Development (LID) for new developments.
4. Recycle all wastewater for beneficial reuse by 2035.
5. Reduce potable water use per capita by 22% by 2025 and 25% by 2035: Offer incentives for water conservation features, including drought tolerant landscaping, permeable materials in standard parkway design guidelines, street trees, infiltration, greywater, and water-saving plumbing.
6. Close oil and gas wells and injection wells near aquifers as a top priority.
7. Create a Master Plan to develop the full potential of integrated water management to infiltrate the ground and recharge aquifers; support reforestation and restoration of watershed ecosystems; conserve and protect groundwater resources, and clean up creeks, streams, and estuaries.
8. Support Santa Clara River Loop Trail and Ventura River Trail Development

Economic Vitality:

1. Agricultural Diversification should include reference to regenerative practices to create biodiversity with opportunities for community members to visit farms.
2. Small Business Promotion. Support approval of caretaker residential space on business property to reduce VMT and more financial strength for small businesses.
3. Green Economy. Prioritize youth and immigrants for workforce development in industries that promote and enhance environmental sustainability, including GHG reductions, climate adaptation, resiliency and local renewable energy generation, storage and distribution, including solar power, wind power, wave energy, regenerative organic farming and value-added agriculture-related activities, and other appropriate renewable sources.
4. Maritime Economy. Facilitate a sustainable maritime economy using restorative aquaculture techniques that restore ocean health and biodiversity while reviving pre-human fisheries abundance. For example, restore sand-bottom kelp forests and increase kelp forests with flexible floating fishing reefs where the seafloor is otherwise too deep for kelp.
5. Promote Fire-Resistant Infill and Revitalization. Encourage infill development that serves as firebreak rather than as additional fuel for wildfires.
6. Create a Collaborative Structure for Innovation for a Resilient Future. The structure should be able to make decisions and create a way forward for zoning, building and materials and environmental health to allow options for a resilient future, include government officials, innovators and public as described in submissions from Sustainable Living Research Initiative.
7. Parking Infrastructure. Develop parking policies to reduce single occupancy trips associated with employees and business activity to reduce Vehicle Miles Traveled.
8. Master Plan for Distributed Energy Resources and Community Microgrids. Prepare a map of siting options for renewable energy generation and storage facilities and coordinate the identification of financing options for renewable energy resource development, including solar, wind, wave, storage and community microgrids both in front of and behind the meter.

In summary, with the accelerating tipping points, we cannot go half-way in our vision. We need extraordinary courage to set goals we can hang our hopes and efforts on. We want completeness and clarity so we can see how the emissions reduction plan adds up. We want respect for climate science to tell us the truth. We want more ambition. A 2016 decision of the state legislature in SB32 is just not good enough as a goal. We want to see a systematic plan that will assure carbon neutrality no later than 2045.

You can view each petition signer and the comments they left you below.

Thank you,

Christopher Tull

Leicy

72. Michelle Cabrera (ZIP code: 93001)

73. Jack Weber (ZIP code: 93023)

Climate policy must be a priority; cease all fossil fuels and witch to renewables and make biking more safe! Thank you...

74. Jackson Piper (ZIP code: 91320)

This general plan will shape how development occurs in Ventura County in the near future and will affect the lives of County residents beyond the timeframe of the plan. It is essential that the plan acknowledges and does everything possible to prepare Ventura County and its residents for the dangers that we face due to climate change - whether or not some of our fellow residents wish to acknowledge that danger or our agency as a society in working to minimize its impact. Please improve upon the Draft General Plan by incorporating the suggestions of the Climate Hub into the final document, so that Ventura County and its residents can more effectively protect this place that is special to all of us.

75. Judy Duerr (ZIP code: 93004-1228)

101. Kate Higgins (*ZIP code: 93004*)

Vote Kim Stephenson for Cty Supervisor, District 3

102. Kathleen Wheeler (*ZIP code: 93003*)

103. Kaysha Farala (ZIP code: 93033)

Dear Ventura County Supervisors,

Please care about the effects of climate change and the negative impact it has been making on our global warming. Please consider our effective solutions to benefit our humanity and biodiversity.

Sincerely,

Kaysha

104. Keith Nieves (ZIP code: 93001)

105. Kristen Kessler (ZIP code: 93004)

106. Katharine Merrill (ZIP code: 93033-7965)

We need to create a climate plan that is grounded in good science, and that means counting all the green house gas emissions from all sources.

107. Katherine Mack (ZIP code: 03023)

108. Kathleen Nolan (ZIP code: 93023)

109. Layla White (ZIP code: 93030)

Dear Ventura County Supervisors,

Please consider taking care of our climate and reducing the effects of global warming.

Sincerely,

Layla

110. Krystal Anderson (ZIP code: 92071)

Dear Ventura County Supervisors,

Please consider the impact of global warming effecting our climate and the area we live in. Please consider our effective climate solutions that would benefit our humanity and biodiversity.

Sincerely,

Krystal

111. Diana Kubilos (ZIP code: 93004)

112. Kevin Ward (ZIP code: 93036)

The time is now for transitioning to non-fossil fuel products, all of them.

Solar, permaculture and voting for Bernie is a good defense against global warming already evident in fires, floods and, like Coronavirus, microbes. Any delay will make the US complicit with chosen

extinction. Think Green New Deal or nada.

113. Kristofer Young (ZIP code: 93023)

The climate portions of the general plan lacks specific, critical goals and mechanisms to ensure achieving them. We do not have time to waste.

114. Kyle Pobirs (ZIP code: 93004)

115. Lauren Mendez (ZIP code: 93030)

116. Lorren Carter (ZIP code: 92064)

Dear Ventura County Supervisors,

Global warming is happening right now we would like for you to consider our climate solutions, so we can live and breathe in a healthier and cleaner environment.

Sincerely,

Starsha

117. LeeAnne Christensen (ZIP code: 93021)

Olivia

154. Celia Ortenberg (*ZIP code: 93030*)

155. Pamela Lopez (*ZIP code: 91362*)

156. Pam Shellenbarger (*ZIP code: 93001*)

157. Paul Aist (*ZIP code: 93004*)

158. Margaret (Peg) Strobel (ZIP code: 93003)

The General Plan must take into account rapid, serious changes--drought and wildfires being the most obvious--from climate change. Since agriculture is a critical part of our economy, attention must be paid to that industry. Also important will be funding a way to seriously reduce oil and gas production, since it contributes to climate change. Plans to train workers to transition to new economic opportunities from climate-friendly industries must be planned. New and existing housing needs to be considered (weatherization to reduce electrical use from air conditioning). Climate change will impact everything that county government does.

159. Phil McGrath (ZIP code: 93010)

160. Rachelle Feria (ZIP code: 93030)

Dear Ventura County Supervisors,

Please consider the impact of global warming effecting our climate and the area we live in. Please consider our effective climate solutions that would benefit our humanity and biodiversity.

Sincerely,

Rachelle

161. Randall Edwards (ZIP code: 91362)

162. Ray Powers (ZIP code: 93023)

A thorough analysis and comprehensive climate action needs to be part of the general plan update. What's is currently being proposed is not sufficient.

163. Ricardo Lopez (ZIP code: 93030)

Dear Ventura County Supervisors,

Please care about the effects of climate change and its negative impact towards global warming.

Sincerely,

Ricardo

164. Robert Dodge (ZIP code: 93023)

Climate change and its effects are one of our greatest existential threats and we must move away from a carbon based extractive economy as soon as possible. We urge you on behalf of the health and wellbeing of Ventura County and all of our citizens to adopt the strongest possible environmental protection in the Draft General Plan.

165. Ron Whitehurst (ZIP code: 93001)

We need to move to regenerative organic farming and landscaping to re-establish the small water cycles.

166. Ron Merkord (ZIP code: 93015)

Rising CO2 levels will soon have consequences for everyone, and Ventura County will see the first of

some of these effects, like increased wildfires and rising sea levels. We need to quit waiting for someone else to do something about it. Our own General Plan update is a great place to start.

167. Rominck Callo (*ZIP code: 93033*)

Dear Ventura County Supervisors,

Please consider taking care of our climate and reducing the effects of global warming.

Sincerely,

Romnick

168. rosemary fields (*ZIP code: 93004*)

Climate change affects the entire world all animals and humans.

169. Siomara Ardon (*ZIP code: 93033*)

Dear Ventura County Supervisors,

Please care about the effects of climate change and its negative impact towards global warming.

Sincerely,

Siomara

170. Scott eckersley (*ZIP code: 93023*)

171. Karen Karayan (*ZIP code: 93060*)

This is one of my top concerns! I worry about our children and their children's world if we don't do as much as we can to protect and heal our world! Ventura County can be one of the leaders in this effort!

172. Sarah Fleury (*ZIP code: 93060*)

173. Sasha Phan (*ZIP code: 93033*)

Dear Ventura County Supervisors,

Please consider taking care of our climate and reducing the effects of global warming.

Sincerely,

Sasha

174. Sonia Kroth (*ZIP code: 93001*)

175. Sharon Ray (*ZIP code: 93105*)

176. Starsha Farala (*ZIP code: 93033*)

Dear Ventura County Supervisors,

Please care about the effects of climate change as it is currently happening. Please strongly do something about the impact towards global warming in our environment.

Sincerely,

Starsha Farala

177. steve nipper (*ZIP code: 93023*)

Because it's the right thing to do!

178. Steve Pinsky (*ZIP code: 93001*)

179. Kristin Storey (*ZIP code: 93023*)

180. Susan Williamson (*ZIP code: 93023*)

Get with you guys! Ventura is a coastal city! Duhhh. You need to host a climate convention to get input on what needs to be done in VC!

181. Susan Curtis (*ZIP code: 91361*)

182. Francesa Gonzales (*ZIP code: 93033*)

Dear Ventura County Supervisors,

Please care about the effects of climate change and the negative impact it has been making on our global warming. Please consider our effective solutions to benefit our humanity and biodiversity.

Sincerely,

Francesa

183. Arthur Snyder (*ZIP code: 93036*)

Global warming is an existential threat.

184. Paul Burke (*ZIP code: 93012*)

185. Tessa Salzman (*ZIP code: 93001*)

186. Tina Frugoli (*ZIP code: 91362*)

187. Catherine Myers (*ZIP code: 93004*)

188. theresa hartigan (*ZIP code: ?93022*)

189. thomas miller (*ZIP code: 93004*)

190. Thomas Seigner (ZIP code: 91361)

Each new climate study outlines a more dire situation than the previous study. Even if we went carbon neutral today, future generations will still experience hardships we have not. NO MORE NEW FOSSIL FUEL PRODUCTION IN VENTURA COUNTY.

191. Tamara Hoyt (ZIP code: 93001)

Please address the climate crisis now

192. Todd Shuman (ZIP code: 93010)

I endorse this petition! It is time that Ventura County increase its commitment to reduce GHG emissions ...

193. Christine Samusick (ZIP code: 93001)

We need a desalination plant. Yesterday.

Water recycling must be encouraged and accommodated.

All styrofoam must be banned.

This is a partial list of actions that will help Ventura through this continual drought and help ease the burden on our landfill.

194. Vicki DeBear (ZIP code: 91311)

195. Vilma Pineda (ZIP code: 93033)

Dear Ventura County Supervisors,

Please care about the effects of climate change and its negative impact towards global warming.

Sincerely,

Vilma

196. Lori Bates (ZIP code: 93035)

197. Margot Davis (ZIP code: 93001)

The planning commission, or whoever it was that drafted the DEIR , I don't understand how they could have so missed the boat? I hope the board of supervisors will not miss the boat entirely and OK this general plan update the way it stands

198. Wilson Altice (ZIP code: 92128)

Dear Ventura County Supervisors,

Please care about the effects of climate change and the negative impact it has been making on global warming. Please consider our effective solutions to benefit our humanity and biodiversity.

Sincerely,

Wilson

Ventura County Board of Supervisors
Attn: RMA Planning Division
General Plan Update
800 Victoria Avenue L#1740
Ventura, California 93009-1740

Dear Board of Supervisors and Staff:

We are writing this letter to urge the Board of Supervisors to reconsider moving forward with the Draft General Plan EIR. The draft EIR has been accelerated to the point that too many issues and impacts have not been properly addressed or studied. These impacts and the corresponding mitigation measures will have severe impacts to land owners and especially those, like us in the agricultural industry and other productive economic segments.

Our family has been involved in the agricultural industry for more than 100 years in Ventura County. We have owned numerous land holdings that remain in the family to this date. We have farmed throughout Ventura County and hope to continue to do so in the future.

The Draft EIR is deficient on many levels. CEQA requires that all mitigation measures must be technically and economically feasible. Numerous proposed mitigation measures are neither. We have in the past attempted to identify land and any owners that would be open to sell their development rights for land that was converting from agricultural to commercial use. Not only did we not find anyone that would do so, no one would even quote a price. The only positive response from numerous land owners were that you can buy my property for full market value and then you can do what you want. There is not a project that can be built by adding double land cost to the equation. This was very recently experienced based on proposed policies at LAFCo. These policies were eventually not enacted due to the inability to purchase development rights in an economical feasible manner. This was when LAFCo was contemplating an acre for acre ag preserve. The new policy that is proposed in the 2040 General Plan is requiring 2 acres for every 1 acre of land converted from ag to any other use. This will eliminate the ability to add any new required ag buildings or even farm worker housing. The Draft EIR must study these impacts, since they are not feasible.

The Draft EIR also deals with water in a manner that is not properly studied. There is no analysis on increased water costs and diminishing availability of water. Without reasonable water costs and supply, there is no agricultural industry.

The General Plan indicates that agriculture is a high priority in the County. However, new policies and requirements in the General Plan add additional mitigation measures that will make ag virtually impossible. These include new setbacks, limiting types of fumigants pesticides and fertilizers. The General Plan also requires the conversion of all farm equipment to be all electric. Again, not feasible. The costs to purchase new pumps, farm equipment and other existing fuel using equipment will increase operational costs to a point that the County crops will not be competitive in the open market. These new mitigation measures are not sufficiently studied and again are not economically feasible.

The Draft EIR is extremely difficult to read and understand. The background reports are lacking in depth of what has been studied other than numerous general statements and very poor mapping. Detailed studies must be added to sufficiently identify impacts and the related mitigation measures for both direct and indirect impacts on the agricultural industry. It is our understanding that reports and studies need to be timely prepared. However numerous studies are older than 5 years. Not timely.

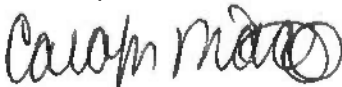

After numerous devastating wildfires over the last few years, which significantly impacted ag, the General Plan continues to lay out limiting mitigation measures for fire prevention. The Wildlife corridor eliminates any ag operation or fire prevention in the proposed corridor areas. This is also a major concern not studied in the Draft EIR.

The Draft EIR for the 2040 General plan does not provide adequate analysis for the expansion of permanent bike paths and pedestrian walking trails throughout the County. These impacts are very severe due to constant conflicts from trail users and ag operations. Spraying, dust, odors from ag operations, along with impacts created by the trail users. These are usually theft, vandalism, litter and pet waste. The proposed mitigation measures require additional setbacks from these trails which renders additional land unusable for ag operations.

In addition to the above comments on the agricultural aspects and related land use concerns of the DEIR, the undersigned is also a mineral owner directly interested in the impacts on oil and gas production of the DEIR and related General Plan 2040 proposed provisions. In these documents there is a total failure to address the economic impacts of the various policies proposed in violation of the requirements for this process, including but not limited to the loss of royalty income to a large group of County residents. I join in the detailed comments on the various deficiencies and concerns identified in the DEIR as described in the concurrent submissions on behalf of Aera Energy and other operators delivered this week to the County.

Please look at the long-term consequences of these General Plan policies and mitigation measures. We formally request additional studies and a revised Draft EIR that will properly look at these and many more issues. The DEIR must be corrected with details of the revisions. Then it can be recirculated.

Sincerely,

Carolyn Diacos

Ventura County Board of Supervisors ,

206 people have signed a petition on Action Network telling you to Petition to VC Supervisors and Planners about VC2040 Draft General Plan and EIR.

Here is the petition they signed:

With worsening climate change impacts, we reiterate and amplify the concerns the people expressed in January of last year about “climate change

and GHGs, and the effects of continued oil and gas extraction including secondary effects related to climate change, air quality, water quality, water supply, traffic, noise, odors, aesthetics, and hazards.”

Our county is warming faster than any other in the nation, our ocean is becoming more hostile to marine life, our last drought was the most intense and lasted longest, and our history of costly floods will be dwarfed when future atmospheric rivers pour over our valleys. Our house is on fire. We need a thorough plan and environmental impacts analysis based on the latest science.

Ventura County’s plan matters. Our larger cities are making climate action plans and look for your example of leadership. The environmental impact from what we do to mitigate climate impacts at the global scale is profoundly influential in trying to stop runaway climate change. This is explained in a new report Insights from the California Energy Policy Simulator about the role of the State of California in the world. Ventura County as a local government hit hardest by climate impacts must step up and meet serious goals. “Insights about California’s climate policies are at the forefront of global efforts to battle climate change. The state’s leadership and success so far have helped maintain momentum despite political headwinds. If California faltered, global efforts to reduce GHG emissions would be dealt a major setback. Meanwhile, the severe risks from runaway global warming are becoming more tangible as the state suffers from wildfires supercharged by climate change.”

A. Four Overall Comments:

We are grateful for the expertise at the law firm of Shute, Mihaly and Wineberger retained by CFROG regarding CEQA. We have appreciated their past comments. We join them in continuing to request the following:

1. Count ALL GHGs that result from activity in our county: Count all burning of oil and gas originating in our county and count all fugitive methane from wells in our county and from methane entering our county that was not counted at the jurisdiction of origin. Do the math on the GHG footprint for heavy exports. We want to mitigate our fair share of all climate impacts from activities within Ventura County. We have to know what they are. Worrying about double

counting is not acceptable. Just worry that you haven't counted every cause of climate impacts that we are morally and legally responsible to mitigate with a comprehensive inventory and a systematic plan.

2. Use the latest science to calculate GWP of methane: The global warming potential of GWP is nearly 40 percent greater than what you are using. The International Panel on Climate Change states that over a 20 year period, methane has a GWP of 84 compared to carbon dioxide (up from their previous estimate of 72). The US EPA estimates it at 87 and recent scientific experts put the estimate at 96. We must know the true environmental impact of methane emissions. A complete and scientifically valid GHG inventory is required for a CEQA-compliant Climate Action Plan.

3. Use the emissions reduction goal from Governor Brown's Executive Order B-18-55 "to achieve carbon neutrality as soon as possible, and no later than 2045, and achieve and maintain net negative emissions thereafter. This goal is in addition to the existing statewide targets of reducing greenhouse gas emissions." It is an inadequate compromise, but not as much as the SB 32 goal of 80% below 1990 levels by 2050. City of LA plans to stay within a net zero carbon budget between now and 2045. The proposed GHG reductions in the VC2040 Draft of 41 percent below 2015 levels by 2030, 61 percent by 2040, and 80 percent by 2050 are not ambitious enough for us to do our part to mitigate the climate chaos happening faster than scientists have predicted.

4. Policies and programs must meet the goal: It does not take an in-depth analysis to see that this plan will not achieve the 2030 goal of 40% reduction in GHGs below 1990 levels. A new report Insights from the California Energy Policy Simulator shows that the State of California will fall short of that goal by at least 15 and as much as 45 MMT CO₂e. We have and continue to advocate for a goal aligned with Governor Brown's Executive Order to achieve carbon neutrality as soon as possible and no later than 2045.

B. Some Comments about Impacts and Mitigation

The environmental impacts that concern us are those resulting from governments not making and carrying out plans to mitigate climate change. Your draft analysis does not include most of them. Table B in the Executive

Summary is not even half finished. Some of the more serious impacts are missing from the draft analysis. Here are a few of our concerns:

1. Aesthetics, Scenic Resources and Light Pollution and Agriculture and Forest Resources: Mitigation programs are needed to protect our resources from degradation from significant climate impacts. The loss of soil in particular is associated with the downfall of civilizations.

2. Air Quality: The emissions impacts from exceeding criteria pollutant thresholds and also greenhouse gases seem significant and can be mitigated.

3. Biological Resources: The new implementation program is a good start to “update the Initial Study Assessment Guidelines, Biological Resources Assessment report criteria and evaluate discretionary development that could potentially impact sensitive biological resources”. Two kinds of impacts are missing. 1) Climate Change. A major mitigation is the restoration of wetlands which should be at a 2:1 or greater ratio. Stormwater management is another mitigation that reverses the loss of vegetation from drought and floods and supports the restoration of all of the indigenous biology that makes an ecosystem function to maintain the small water cycles. 2) Toxic Pesticide and Herbicide Use and Drift. This must be part of the agenda of a Program for Protection of Sensitive Biological Resources to promulgate the mitigations provided by Integrated Pest Management. Pest management policy must align with the recommendations of the California Department of Pesticide Regulation Roadmap for Integrated Pest Management some of which have climate mitigation co-benefits.

4. Energy: We want a workshop to learn how it is deemed less than significant to allow wasteful, inefficient, or unnecessary consumption of energy resources.

5. Greenhouse Gas Emissions: The climate change impacts are so dire that the mitigations need to be benchmarked to be achieved before it is too late to reverse runaway climate chaos. At minimum we demand a systematic plan for decarbonization of county facilities and electrification of the transportation system.

6. Hazards, Hazardous Materials, and Wildfire: The impacts of toxic explosions, leaks, and spills and the drift of regulated materials and the ignorance of the public about toxic impacts must be addressed where feasible through mitigations that regulate the use and transport of hazardous materials. We have recommended feasible mitigations for people being exposed to the risk of wildfires that have not been accepted by decision-makers.

7. Hydrology and Water Quality: Impacts from climate change and poor land management have have led to grave threats to water supply and water quality. These are highly significant--ground water overdraft, overuse and degradation of water quality, erosion, flooding, and siltation. (Impact 4.10-12) The failure to restore small water cycles to keep stormwater in the uplands and maintain forest health is one of the most serious impacts being mitigated in many places through a paradigm shift about stormwater management. Mitigation is essential--water is life. It requires an integrated water management plan that involves every sector working on every mitigation of which we are aware.

8. Land Use and Planning We want an analysis of incompatible land uses and new development with negative health implications. Closing wells near sensitive sites is a mitigation. Environmental Justice is not examined in the draft EIR.

9. Mineral and Petroleum Resources: We want an analysis of the impact of the scenario in which wells have been put on hold and the operator cannot close the wells for lack of funds. We have no choice. The wells must be closed properly. Fields must be restored to functioning ecosystems to help mitigate climate change impacts. We need insurance as well as bigger bonds.

10. Traffic and Transportation: Tailpipe emissions is an extremely significant environmental impact. The mitigation aimed for in the CTM-C: Vehicle Miles Traveled (VMT) Reduction Program needs assurances of effectiveness via a clear description of what "conditions warrant providing additional mitigations and programs"? This is far too vague to be a mitigation for this significant

impact. We have no alternative but to reliably cut GHGs in the transportation sector.

11. Utilities: Failure to develop wholesale and commercial scale renewable energy generation and microgrids is a significant environmental impact because it has forced us to have to get our electricity from fossil fuels via transmission lines that spark wildfires. Community microgrids are a feasible mitigation.

12. Waste Management: Failure to properly manage waste has a highly significant environmental impact, especially when it produces methane super-emitter landfills that is driving climate change, but also the failure to reuse and recycle consumer goods and the materials and equipment discarded by commercial enterprises. We need a more comprehensive approach for mitigation of these impacts.

C. The following policy recommendations for the Draft Plan could help the Plan achieve the GHG reduction goals to mitigate climate change impacts and help the EIR be more relevant to the climate crisis.

Land Use and Community Character: We endorse the comments submitted by Bruce Smith to more firmly assure preservation of agricultural land and open space. We point out the lack of analysis of Environmental Justice policy issues.

Circulation, Transportation, and Mobility:

1. No overriding considerations should allow a project to NOT reduce VMT unless all of the vehicles have zero emissions that will use the proposed project.
2. CTM 3-9 to widen SR 118 has a significant environmental impact.
3. Benchmarks to reduce VMT need to be more clear and the plan needs a review with public input every two years until 2028 and then no longer than every five years.
4. Parking programs should be included in ways that reduce single-occupancy car trips.

Public Facilities, Services, and Infrastructure:

1. Enroll residents in a program to reduce CO2 emissions in their neighborhoods. Ex: Cool Block or Transition Streets.
2. PFS 2.1 must be revised to say include rather than encourage 'Sustainable Plans and Operations' in order to be considered a mitigation of climate change impacts from greenhouse gas emissions.
3. Policy PFS 7.1 should be revised to delete the need for access to gas. The environmental impact from use of natural gas requires carbonizing buildings beginning with no gas connections to new residences . It is therefore contradictory to ensure access to gas.
4. Local renewable energy generation must be part of the mitigation plan for reducing transmission facility fire hazard risk. This is not the same as "Smart Grid Technology". You need experts who know the cutting edge of this field to help write coherent policy on this topic.
5. Zero Waste The County shall achieve zero waste (via a suite of policies to reduce, reuse, and recycle) with no organic waste going to landfills by 2023
6. Zero Waste Policy for Meetings and Events Design and implement a zero waste policy for meetings and events sponsored or permitted by the County to minimize waste and rescue surplus edible food
7. Compostable Take-Out Foodware Require that take-out foodware be made with material compostable in solid waste processing facilities within 60 days
8. Reduce Solid Waste by Phasing Out Single-Use Plastic Evaluate how to best reduce solid waste generation per capita by at least 15% by 2030 including phasing out single-use plastics including but not limited to plastic straws, plastic utensils, plastic take-out containers, and expanded polystyrene
9. Ban Expanded Polystyrene

Conservation and Open Space:

1. Reduce oil and gas production by 40% by 2025 via higher monitoring standards and 2500 ft buffer zones near sensitive sites; reduce production to zero by no later than 2040.
2. Phase-Out of Oil and Gas Production The County shall prohibit new drilling and shall regulate existing wells to assure steady closing of wells beginning near residential and commercial areas.
3. Maintain Policy COS-7.8 as recommended by the Board of Supervisors, so that all newly permitted discretionary oil wells are required to collect gases

and use or remove them for sale or proper disposal instead of flaring or venting. Flaring should be allowed only in cases of emergency or for testing purposes.

4. Maintain Policy COS-7.7 as recommended by the Board of Supervisors, so that all newly permitted discretionary oil wells are required to convey oil and produced water via pipelines instead of trucking.

5. Detect and curb methane emissions from “super-emitter” sites as identified by NASA.

6. Tax oil and gas production, and related uncaptured methane to raise the needed revenues to fund urgent climate programs to replace high-emission vehicles with a priority on trucking and freight companies, fishing businesses, general contractors and K-12 schools.

7. Require a fully accountable performance bond for all new wells to cover cost of closure Cite LAT article (maybe put on website and link to it).

8. Establish an insurance fund that oil and gas producers contribute to that will cover accidents and closing wells if the producer goes bankrupt.

9. Ban gas-fueled lawn and garden equipment. (Ex: City of Ojai)

10. Accelerate capture of legacy HFCs Enlist the public and private to find and destroy existing stocks of HFC's (refrigerant gases with extremely high Global Warming Potential).

11. Develop and adopt building codes based on best practices for use of low embodied carbon concrete and set targets for use of low GHG concrete alternatives. Ex: Bay Area Air Quality Management District and King Co, WA.

12. Encourage climate-safe and climate-resilient development through zoning reform and removal of limits on height, density, and minimum parking requirements to enable and promote walkability and a mix of uses for homes and businesses, parks and transit.

13. Create a master local clean energy siting and funding plan for wholesale distributed solar energy plus storage in commercial scale projects producing energy needs by 2030.

14. Provide energy efficiency benchmarking and rebates for low-income housing and renters as well as low-interest loans for small businesses to reduce energy use; assist owners of existing buildings to switch from natural gas to electricity.

15. Prepare sustainable building, siting, landscaping and passive heating and cooling practice guidelines, with a priority on low-income housing, that reduce

consumption of non-renewable resources and that include climate and fire-safety in pre-approved plans.

16. Energy Efficiency to Reduce Electricity Use Use Energy Efficiency to Deliver 15% of Projected Needs for electricity in the county by 2023; and 30% by 2030.

17. Efficiency Building Standards for Retrofits Prioritize energy and water efficiency building standards and work to retrofit existing buildings.

18. Decarbonize County Buildings Develop a county building electrification plan eliminating natural gas use in County-owned facilities.

19. Decarbonize All Building Types Develop an electrification plan with goals for GHG emission reductions through renewable energy that evaluates and prioritizes programs for local solar, energy storage and demand response (DR) that disconnects all buildings from gas service by 2050. Include incentives for deep retrofits of inefficient buildings.

Agriculture:

1. Integrated Pest Management where toxic pesticides are a last resort.

Create a program that promotes the principles (systems approach, building trust, and effective communication) and pursues the recommendations of the Roadmap for Integrated Pest Management from the University of California and CA Department of Pesticide Regulation. Environmental impacts from toxic pesticides are not described in the Background Report. The Roadmap to an Organic California Policy Report by CCOF Foundation offers information for mitigations and climate action. A workshop is needed.

2. Inorganic Nitrogen Based Fertilizers Set benchmarks for reducing use of inorganic N fertilizer and encourage optimized use of organic and inorganic fertilizer for greatest efficiency in closed nutrient cycles, monitor for nutrient runoff from fields and encourage the use of cover crops and green manure crops to reduce or avoid nitrous oxide (N₂O) emissions and nutrient runoff.

3. Diversified Cropping Systems Encourage farmers to include 1 – 5% of beneficial insect attracting plants in a planted crop, and other methods, such as crop rotation, perennial mowed cover crop in orchards, and integrating multiple species or varieties to enhance the biological and economic stability by spreading economic risk and buffering against pest invasions and extreme weather events, and increase carbon sequestration.

4. Reward Regenerative Farmers with Digestate and Compost from Food

Waste Research feasibility of a program for composting food waste for use by farmers and landscapers who use regenerative practices that sequester certified amounts of CO₂.

Water Resources:

1. At least 30,000 acre-feet per year must come from storm water capture by 2035
2. All rainfall must be retained onsite in soil and reservoirs.
3. Slow It. Spread It. Sink It! The County shall enforce Best Management Practices (BMP) and Low Impact Development (LID) for new developments.
4. Recycle all wastewater for beneficial reuse by 2035.
5. Reduce potable water use per capita by 22% by 2025 and 25% by 2035: Offer incentives for water conservation features, including drought tolerant landscaping, permeable materials in standard parkway design guidelines, street trees, infiltration, greywater, and water-saving plumbing.
6. Close oil and gas wells and injection wells near aquifers as a top priority.
7. Create a Master Plan to develop the full potential of integrated water management to infiltrate the ground and recharge aquifers; support reforestation and restoration of watershed ecosystems; conserve and protect groundwater resources, and clean up creeks, streams, and estuaries.
8. Support Santa Clara River Loop Trail and Ventura River Trail Development

Economic Vitality:

1. Agricultural Diversification should include reference to regenerative practices to create biodiversity with opportunities for community members to visit farms.
2. Small Business Promotion. Support approval of caretaker residential space on business property to reduce VMT and more financial strength for small businesses.
3. Green Economy. Prioritize youth and immigrants for workforce development in industries that promote and enhance environmental sustainability, including GHG reductions, climate adaptation, resiliency and local renewable energy generation, storage and distribution, including solar power, wind power, wave energy, regenerative organic farming and value-added agriculture-related activities, and other appropriate renewable sources.
4. Maritime Economy. Facilitate a sustainable maritime economy using

restorative aquaculture techniques that restore ocean health and biodiversity while reviving pre-human fisheries abundance. For example, restore sand-bottom kelp forests and increase kelp forests with flexible floating fishing reefs where the seafloor is otherwise too deep for kelp.

5. Promote Fire-Resistant Infill and Revitalization. Encourage infill development that serves as firebreak rather than as additional fuel for wildfires.

6. Create a Collaborative Structure for Innovation for a Resilient Future. The structure should be able to make decisions and create a way forward for zoning, building and materials and environmental health to allow options for a resilient future, include government officials, innovators and public as described in submissions from Sustainable Living Research Initiative.

7. Parking Infrastructure. Develop parking policies to reduce single occupancy trips associated with employees and business activity to reduce Vehicle Miles Traveled.

8. Master Plan for Distributed Energy Resources and Community Microgrids. Prepare a map of siting options for renewable energy generation and storage facilities and coordinate the identification of financing options for renewable energy resource development, including solar, wind, wave, storage and community microgrids both in front of and behind the meter.

In summary, with the accelerating tipping points, we cannot go half-way in our vision. We need extraordinary courage to set goals we can hang our hopes and efforts on. We want completeness and clarity so we can see how the emissions reduction plan adds up. We want respect for climate science to tell us the truth. We want more ambition. A 2016 decision of the state legislature in SB32 is just not good enough as a goal. We want to see a systematic plan that will assure carbon neutrality no later than 2045.

You can view each petition signer and the comments they left you in the attached PDF.

Thank you,

Christopher Tull
